Vomiting.—Vomiting was only complained of by patients when there was evidence of grave cardiac disability, and its appearance heralded the end. It occurred—but only as a very late event—in three out of the four patients who died suddenly. One patient ate his breakfast prior to coming to hospital, on his weekly visit, said he felt sick, immediately vomited, and fell dead.

Liver.—Hepatic enlargement was only found when there was other evidence of cardiac failure, except in one case where an alcoholic history, the consistence of the organ and its freedom from tenderness, seemed to justify the additional diagnosis of hepatic cirrhosis.

Spleen.—The spleen was found enlarged and palpable in nine cases. In five of these malaria was known to have occurred in the past, one patient was known to have hepatic cirrhosis, which condition was thought to account for the enlargement. Four cases were diagnosed as subacute bacterial endocarditis, and one as ulcerative endocarditis. In this connexion the frequency with which a past malarial history is obtained in these cases of subacute endocarditis appears to be greater than the fortuitous coexistence of the two diseases would warrant. There seems evidence for the belief that malaria in aortic valve lesions of old standing is liable to determine the onset of this complication.

Eyes.—Routine examination of the fundus oculi was made and pulsating retinal vessels were occasionally observed but in six cases definite retinal changes were found—1 bilateral syphilitic choroiditis, 1 bilateral optic atrophy (tabetic), 2 retinal hæmorrhages (renal; both cases dead), 2 retinal hæmorrhages (in subacute endocarditis; both cases dead).

Kidney.—The renal function was investigated by the urea-concentration test in 39 cases. Response was found to be below normal in eight cases—3 of renal disease, 1 with auricular fibrillation, and 4 with red blood cells also present, and thought to be cases of subacute endocarditis.

Tenderness.—Hyperalgesia was investigated in all cases and in only seven was any tenderness elicited, although so many of the patients complained of præcordial pain or discomfort. In two cases which gave a history resembling, if not identical with, angina, both showed marked tenderness. Two other cases, both with large hearts, showed a tender spot at the left seventh costochondral junction. The rest had only slight præcordial tenderness.

Exertion.—In nine cases the exercise tolerance was quite good, and these patients possessed little or nothing in the way of symptoms except one patient, a tabetic. The rest of the patients had a very poor response to exertion, becoming distressed and breathless on very slight provocation.

X ray.—The routine radiographic examination which was made gave most valuable information, both as finally deciding the presence or absence of an aneurysm and also in corroborating the clinical findings with regard to the cardiac size and shape. The typical aortic form of heart was reported in almost every case.

Other Diseases and Mental Change.

Other diseases were found to coexist in these patients, but always in some way related to the cardiac condition. Thus, to recapitulate: 1 ulcerative endocarditis, 4 subacute endocarditis, 1 active syphilis, 1 tabes, 1 hepatic cirrhosis, 2 nephritis. In no case was any mental change noticed in the patients except in the tabetic, who constantly professed himself very fit indeed in spite of his manifestly parlous state. He showed no other indications of G.P.I. beyond this and his optic atrophy.

Diagnosis.

Very little evidence is available to show how frequently errors of diagnosis are made in aortic disease. Several cases had murmurs difficult to hear either by direct auscultation or with any form of stethoscope. Much help was obtained by bending the patient well forward and listening along the aortic course, but it is essential to keep a firm grip on these patients, as their vertigo is always increased by this manœuvre, and they are very liable to fall. In one case at least a diagnostic error was probably committed, and this in spite of the fact that the possible fallacy was thought of and discussed. The patient had advanced renal disease with retinal hæmorrhages, urgent dyspnœa, and signs of a very large pericardial effusion. There was a systolic murmur and an impure first sound at the apex. Diastolic murmur was not audible at the base, but was heard at the fifth left costal cartilage, soft and blowing in character. The second sound was easily heard. The possibility of pericardial friction was discussed, but ruled out on account of (*a*) the character of the sounds, and (*b*) the size of the effusion. Operation was undertaken later to remove the pericardial fluid in the hope of relieving the respiratory distress. This was to some extent successful, but the patient died four days later. At the post-mortem there was some sclerosis of the aortic valve segments, but no regurgitation to the water test.

Circulatory Conditions.

Much help was obtained from electrocardiographic tracings, conditions being revealed which could not otherwise have been made out.

P.R. interval.—No case of heart-block was found in this series, but the P.R. interval exceeded the normal in four cases—one of rheumatic disease with left-side preponderance who remains well, two of arterio-sclerosis (one died from heart failure, the other shows retinal hæmorrhages), and one case of subacute endocarditis who died suddenly.

Inversion of T.—The inversion of T in lead 2 in the absence of digitalis administration was found in four cases—1 syphilitic aortic disease with right-sided dominance, 1 rheumatic disease with left-sided preponderance, cardiac asthma and angina, 1 arterio-sclerosis, and the case of pericardial effusion which showed no aortic incompetence at post-mortem. All four of these cases were clinically very ill.

Q.R.S. interval.—No case in this series was found showing a Q.R.S. complex exceeding the normal period.

Left-side preponderance.—It was thought that if a left-sided hypertrophy were the response to mechanical aortic damage, its absence should indicate a want of recuperation on the part of the patient; except where a coexisting mitral stenosis might occasion a right-sided preponderance (R.S.P.). Investigation along these lines gave the following results: General condition remarkably good in 8 cases. R.S.P., 3; L.S.P., 3; no change, 2. General condition remarkably bad in 11 cases. R.S.P., 2; L.S.P., 8; no change, 1. Obviously the degree of regurgitation would form a large factor in the resulting hypertrophy. Estimation of the grade of regurgitation was attempted with the following results: Slight, 15 cases: L.S.P., 6; R.S.P., 5; no change, 4. Grave, 25 cases: L.S.P., 17; R.S.P., 4; no change, 4. Of those cases showing a grave degree of regurgitation and no change in the electrocardiogram two are already dead. Among the tracings a left-sided preponderance was found 21 times. In 15 of these the cardiac enlargement was marked and aortic in type, in 2 cases the clinical enlargement was slight, while in 4 cases no enlargement was made out. Of these 21 cases 5 had a presystolic murmur; 8 were thought to be rheumatic, 9 syphilitic, and 4 arterio-sclerotic.

Right-side preponderance.—Nine such cases were found; 4 had a presystolic murmur, 5 were considered rheumatic in origin. There was no evidence for regarding the R.S.P. cases as more serious than those showing L.S.P.

P.-wave or auricular wave.—An examination of the P. wave as regards magnitude and duration gave no help as regards the presence or absence of true mitral stenosis. Seventeen cases gave a P. deflection exceeding 3 mm. in lead 2, and of these only 6 had a presystolic murmur. In 5 the P. wave was split, but only one had a presystolic murmur, and animal, not because its presence is necessary for the life of all the cells of such an animal, but because its presence is necessary for the normal functioning of lymphoid tissue. In other words, the term "deficiency diseases" is, like the term "vitamin," a misnomer. These diseases have their origin, like other diseases, in specific lesions. These lesions may be induced by different agencies of which a deficiency in vitamins is only one.

THE EFFECT OF B-VITAMIN ON THE APPETITE.

BY SAMSON WRIGHT, M.R.C.S. ENG.,

SENIOR DEMONSTRATOR OF PHYSIOLOGY, MIDDLESEX HOSPITAL MEDICAL SCHOOL.

(*From the Department of Physiology.*)

YOUNG rats fed on diets deficient in vitamin B lose weight after varying periods of time and finally die in a condition of emaciation. It was thought interesting to determine whether diminished food intake was a contributory factor in this loss of weight. Young rats from the same litter were employed. All the animals were fed for the first two weeks on a basal ration containing vitamin A and B in the form of cod-liver oil and marmite respectively. The basal ration was the one usually employed by workers in this field and contained purified caseinogen, starch, and a salt mixture. As a source of fat containing no vitamin A a specially prepared form of palm-kernel oil was used. It consisted of an edible quality of palm-kernel oil which had been heated for four hours at 160° C., and subsequently treated with superheated steam at 230° C. Experiments (unpublished) have been carried out with this substance, which show that palm-kernel oil, after such treatment, is quite free from the fat-soluble A vitamin.

Method of Experiment.

The rats were kept in metabolism cages in a warm room. The food—placed in beakers which were firmly fixed in the cage so that no spilling could occur—was presented twice a day, in the morning and evening, and on each occasion was allowed to remain in for a period of one hour. The average daily intake of each animal on such a diet was thus determined. After two weeks both vitamins were removed from the diet of certain of the rats. The others were kept on the diet rich in vitamins, and served as normal controls. At once, within 24 hours, the animals receiving the vitamin-free diet showed a considerable fall in their food intake. The level of intake remains low throughout the period that this diet was maintained. At the same time there was also a steady decline in the weights of the animals. Thus, one of the rats which had been consuming on an average 9·37 g. daily now only took 5·64 g.; during this period, too, its weight fell from 55 g. to 43 g. The control animal fed on a diet rich in vitamins maintained a daily intake of 14·20 g. and its weight rose from 72 g. to 110 g. (Table I.)

TABLE I.

Week of experiment.	R 1.			R 2.		
	Diet.	Average daily intake.	Weight 36 g.	Diet.	Average daily intake.	Weight 39 g.
		g.	g.		g.	g.
1	Normal	8·95	48	Normal	12·6	57
2		9·79	55		13·1	72
3	Vitamin-free	4·8	53		11·98	83
4		6·41	46		13·7	99
5		5·73	43		15·94	110

A trace of marmite was now added to the diet of the vitamin-free animals. It was administered separately in the mornings about two hours before the first feed. The marmite was eagerly consumed by the animals. The intake of the basal ration at once rose and at the same time the weights began to improve. The improvement in intake was as rapid in onset as the fall had been after the removal of the vitamins. In the case of the above-mentioned animal the intake rose from 5·73 g. to 8·66 g. daily. The weight rose from 43 g. to 59 g. in a period of three weeks. It should be noted that the intake never reached the level attained during the period when both vitamins were administered. (Table II.)

TABLE II.

Week of experiment.	R 1.			R 2.		
	Diet.	Intake.	Weight.	Diet.	Intake.	Weight.
		g.	g.		g.	g.
6	Vitamin-free and trace of marmite	10·22	51	Normal	14·6	115
7		7·66	55		13·8	120
8		8·22	59		14·2	123

Previous Experiments Summarised.

The literature on the subject is not very extensive.

Drummond[1] has investigated the protein metabolism in rats fed on diets containing no vitamin B. He was unable to detect any abnormality sufficient to account for the inability to maintain weight. During the course of these experiments he noted that the food-consumption of the rats fed on the diet deficient in vitamin B was reduced. Increased consumption could be brought about by the addition of flavouring agents to the diet. The same effect was produced by the addition of water-soluble vitamin B. Only when the vitamin was added, however, was there any resumption of growth. Drummond[2] has also shown that there is no disturbance of fat absorption in the absence of the fat-soluble vitamin A from the diet.

Karr[3] carried out experiments on dogs, in which weighed quantity of food deficient in water-soluble vitamin B was presented to the animals. At first the portion was completely consumed. Subsequently most of the animals refused to take a part, and ultimately failed to eat any. The desire to eat could be restored on addition of vitamin B. The same result was obtained if the vitamin was presented apart from the food. In the case of one animal, although the intake remained normal, the usual symptoms produced by the vitamin deficiency made their appearance.

These tubes were incubated for 18 hours, and a loopful was then plated on MacConkey. Time did not admit of the use of the brilliant-green method in all cases. It would appear that this method leads to an increase in the number of non-lactose-fermenters isolated. The control experiment of incubating plain peptone-water tubes for the same period was, however, not performed. From the MacConkey plate colonies were picked off and planted into glucose peptone water, and, after 24 hours' incubation, a loopful from the glucose tube was plated on MacConkey, and a single colony selected from this final plate for complete investigation. All sugar tubes were sterilised by heating them to 100° C. on three successive days for 15 minutes. The sugars used were glucose, mannite, maltose, saccharose, and dulcite, and were supplied by Baird and Tatlock, litmus being used as the indicator. The sugars were present in 1 per cent. solution, except in the case of lactose, which was added to 3 per cent. All sugar tubes were incubated for three weeks before they were finally discarded; this revealed the presence of numerous late-lactose-fermenters, which on MacConkey and for the first few days in the 3 per cent. sugar tube produced no recognisable fermentation of lactose.

Indol.—Tested for by the ether-extraction method. The Voges-Proskauer test was applied to some of the organisms, a three-days' growth at 37° C. in glucose broth being well shaken up with a 10 per cent. caustic potash solution. No positive results were obtained with this test with any of the organisms described below; it is possible that the potash solution was not sufficiently strong.

Motility.—Investigated in hanging-drop preparations, 18-hour broth cultures being used. In certain doubtful cases control preparations were made in 5 per cent. carbolic acid.

Gelatin.—Twenty-five per cent. gelatin was employed, to ensure the medium remaining solid at laboratory temperatures. Tubes were kept under observation for six weeks.

Lead acetate agar.—Slopes were inoculated between the agar and the glass. Blackening was observed both in the medium and in the surface growth which developed at the point of insertion of the needle. It appears advisable to add the acetate as late as possible to the cooling agar, many batches proving useless in which the temperature of the agar appeared to be the disturbing factor. A time-limit seems necessary in employing this test, as many organisms will produce blackening if left for three or four days on the agar.

All agglutination tests were performed by the macroscopic method with unit volumes of 0·2 or 0·3 c.cm. Normal human serum controls were always employed. The tubes were incubated in a water bath for two hours at 37° C., and then for two hours at 56° C., confirmatory readings being taken overnight. Pipettes with rubber teats, graduated to 0·1 and 0·01 c.cm., were used in making the dilutions. Rabbits were used for the preparation of antiserums, the method of Chick and Dalyell being followed with excellent results.[2] In testing these serums a dilution of 1/4000 was the highest used, complete flocculation at this titre being regarded as sufficient indication for bleeding the rabbit. These locally-prepared serums, preserved with 0·1 per cent. carbolic, retained their efficacy for over a year, even under the inadequate conditions of storage prevailing at the laboratory.

In all, the stools of 38 normal natives have been examined, samples being taken on three successive days in the majority of the cases. Specimens were examined as fresh as possible—usually within one to two hours after the passage of the stool. As "normals" were considered healthy individuals, or hospital patients suffering from mild venereal disease or from minor ailments. Stools from 26 natives suffering from typhoid or dysenteric disease were similarly dealt with. Stools from 12 abnormal Europeans, all of whom were suffering from some kind of intestinal disturbance, were also examined, and one Indian stool from a case of typhoid.

The various groups of organisms will now be considered, and the relative frequency with which each of these groups occurred will be shown at the end of this section in Table II. For the agglutination tests in connexion with Groups 1 and 2 only two dilutions were used, of 1/40 and 1/500, the object being to obtain a rough idea of the serological affinities of the various strains with a minimal expenditure of time. The main characters of the groups are indicated in the subjoined Table I., following upon which will be found a brief account of the serological tests applied to each group. Each case receives a reference number, the various colonies isolated being distinguished by letters. Thus 113a, b, and f, all come from the same individual, No. 113.

Group 1.—Found in 2 abnormal natives, 10 normal natives, and 2 abnormal Europeans. Rabbits were prepared against three strains of organisms of this group—viz., 232e, 234g, and 247c—and the other strains were tested against these three agglutinating serums. Serum 232e gave complete agglutination at 1/500 with strains isolated from six different natives, and gave complete agglutination at 1/40 with a strain from a seventh individual, the 1/500 dilution with this last strain proving negative. With Group 1 strains from eight other natives, normal and abnormal, no agglutination resulted at either dilution. Serum 234g gave complete agglutination at 1/40, nil at 1/500, with a strain from a normal native. With 14 other strains of Group 1, isolated from different natives, normal and abnormal, no agglutination occurred at either dilution. Serum 247c gave complete agglutination at 1/500, with strains from four different normal natives. With eight other strains from different normal natives no agglutination occurred at either dilution.

These experiments showed also that Nos. 232e and 247c were nearly related, if not identical, strains, neither of which showed any serological affinity to No. 234g.

It is thus plain that at least two distinct serological races are included in Group 1, which is of fairly frequent occurrence in normal natives' stools in Uganda. Morgan found organisms of this kind occurring in as many as 11·7 per cent. of his cases, but they always gave a positive indol test.[3]

Group 2.—Found in 7 abnormal natives, 20 normal natives, 3 abnormal Europeans, and 1 Indian. Rabbits were prepared against two strains of this type of organism—viz., 234f and 247d—and the other strains were tested against these serums. Serum 234f gave complete agglutination at 1/500 with one strain (from a different individual); also complete agglutination at 1/40, trace at 1/500 with a strain from another individual; also complete agglutination at 1/40, nil at 1/500 with a strain from a third individual. Serum 247d gave complete agglutination at 1/40, nil at 1/500, with strains from two different individuals.

These experiments showed also that Nos. 234f and 247d have totally different serological affinities. Under the heading "blood cultures" further observations are made concerning this group of organisms.

Group 3.—Found in 2 abnormal natives and 3 normal natives. Rabbits were prepared against two strains, 100H and 113d, which came from a native typhoid and a native dysentery case respectively. Neither serum had any action with the heterologous organism. Serum 113d gave no agglutination with any of the heterologous strains tested, including five sent to me by the pathologist at Nairobi. Serum 100H gave interesting results. With two out of the three strains isolated from Uganda natives this serum gave complete agglutination in 1/1280. These two strains came from different individuals. Complete agglutination at 1/1280 (highest dilution employed) also resulted with one of the five Nairobi strains of Morgan's bacillus, the other four strains giving negative results at all dilutions.

In no case has the serum of the individual, normal or abnormal, from whose stool Morgan's bacillus has been isolated in Uganda given any agglutination with his own strain from 1/20 upwards. All the above agglutination tests were controlled with normal human serum. The third Uganda strain, 261a, isolated from the stool of a normal native, gave no response with either serum, and produced acid and clot in milk. This organism is therefore not to be regarded as a typical Morgan No. 1, and is accordingly not included in the percentages of Table II. Morgan found his organism in as many as 55·8 per cent. of his cases.[3] The recognition of serological affinity between three strains of Morgan's bacillus from natives, one from a native typhoid case in Uganda, one from a normal Uganda native, and the third from a dysentery outbreak in Nairobi is interesting.[1] The rôle played by this bacillus as a pathogenic agent is still doubtful, though workers for the Medical Research Committee have of late advanced reasons for regarding it as of some significance. The scanty evidence put forward above is insufficient to warrant any opinion on this point.

Group 4.—Found in 6 abnormal natives, 1 normal native, and 3 abnormal Europeans. Nos. 113a, 202, 257, and 174 gave no agglutination with either their host's serums or with a Burroughs and Wellcome (B. and W.) Flexner serum or with two locally-prepared Flexner serums. Nos. 211, 212, 213 gave no agglutination with the patients' serums or with B. and W. Flexner and typhus serums. All three organisms gave complete agglutination at 1/320 (highest done) with each of two monovalent serums prepared locally against two strains of Flexner bacillus derived from the Lister Institute.

Pathogeny.

The pathogeny may be considered under five headings, as follows :—

(1) *Rupture of a valve segment.*—One case may possibly have originated by rupture of a valve segment, but there is no conclusive evidence. The patient fell down a cliff side with a machine-gun on Gallipoli in 1915, was picked up unconscious, found to have a cardiac lesion, invalided home and out of the service, and died in hospital from cardiac failure with general anasarca. The diastolic murmur was always high-pitched and musical in quality. No post-mortem was permitted. No history or evidence of past rheumatism or syphilis was obtainable. The total duration of the disease was five years.

(2) *Acute rheumatism.*—There is considerable difficulty in separating the cases due to rheumatic endocarditis from those not so caused. Two methods were attempted, firstly by careful collection of childhood and adult histories with regard to rheumatic affections, including chorea, tonsillitis, scarlet fever, growing pains, &c. Thus 21 cases gave evidence of rheumatic fever : two other cases gave a history of severe sort-throat or scarlet fever which appeared to stand in direct causal relation to the disease. Two cases had suffered two attacks, and one case three attacks, of rheumatic fever. In only one case of the series was a history of rheumatic affections in the family obtained. Of the female cases all were definitely rheumatic in origin, except one case which at the post-mortem was found not to have aortic incompetence. In only 11 of the 21 cases was the cardiac lesion discovered at the time of the rheumatic attack. The second method attempted for separating the cases of rheumatic origin was from the character of the mitral lesion found. Rheumatic endocarditis is more likely to affect the mitral valve, giving rise to stenosis, than any other ætiological factor at present known. Sixteen cases were found to present a presystolic crescendo murmur at the apex. No attempt was made to differentiate the murmur of true stenosis from the Austin Flint murmur. In my opinion it is not usually possible. Of the 16 cases presenting two murmurs, aortic diastolic and mitral presystolic, there was a definite history of rheumatism in 11 cases, a positive Wassermann reaction (W.R.) in three cases, and evidence of arterio-sclerosis in two cases. It is probable that the presystolic murmur heard in the syphilitic and arterio-sclerotic cases was produced by the method to which Flint drew attention. No post-mortem evidence is yet available.

(3) *Syphilis.*—W.R.'s were tested in 45 cases ; 16 of them proved to be positive, 11 being positive 1 in 40 dilution of serum, and 5 positive 1 in 5 dilution. In four cases there was a history of rheumatic fever as well as a positive W.R. ; in two of these the cardiac lesion appeared to be the direct and immediate outcome of the rheumatism, but in the other two the heart lesion was found 18 and 26 years after the rheumatic attack, and was probably syphilitic.

(4) *Arterio-sclerosis.*—Twelve cases were found in which neither of the preceding ætiological factors were active. In seven of these the occupation was known to entail unusually heavy work, but in the other five cases the work was light. Two of these cases were found to have deficient renal function.

(5) *Infective endocarditis.*—With regard to an infective active endocarditis without associated rheumatic phenomena, one case had typical acute fulminating ulcerative endocarditis, and four other cases were regarded as subacute bacterial endocarditis.

Duration.

Of the fatal cases the time during which a cardiac lesion was known to have existed averaged only two and two-thirds years. Taking the whole series together the number of years the lesion was known to have existed at the time of examination averaged three and a half years, the period of collection being eight months. Of the 50 cases six were discovered incidentally in the course of general routine medical examination, and were entirely latent, giving no symptoms recognised by the patient. To this number must be added two other cases similarly found, which could not, on account of their nature, be added to this series.

Symptoms.

Pain.—Not severe in character, but recurring at fairly frequent intervals : pain over the præcordium occurred in 26 cases : anginal attacks in two cases ; three cases complained of epigastric pain.

Dyspnœa.—Occurred in all cases to some degree, reaching a serious point in six cases : asthmatic attacks repeatedly occurred in two cases, both of which also had anginal attacks. Twenty-one of these patients had some degree of orthopnœa, but in only five was it distressing.

Cough.—Troublesome from time to time in almost all the cases, but forming only in very few the outstanding feature of the disease, even for a short time.

Vertigo.—An almost constant symptom ; in several cases the reason for seeking medical advice.

Predisposing Causes.

Various causes have been regarded as contributing either to the actual production of disease or to the final breakdown.

Tobacco.—So far as this series is concerned, tobacco did not appear to affect the issue. Patients who had been heavy smokers, using more than ten cigarettes per day, or three ounces of tobacco per week, were not found ; but in all cases where the cardiac condition was giving rise to symptoms the patients volunteered the information that they had given up smoking as they found that it made them worse.

Alcohol.—There was good reason to believe that alcoholic excess had occurred in five cases. On the other hand, 17 cases stated that they were lifelong abstainers.

Games.—In no case was there reason to suppose that playing games stood in any causal relationship to the disease. Neither could it be used to determine the onset of the lesion ; several patients who had suffered an attack of rheumatic fever in early life played games successfully and without any difficulty in adolescence.

Work.—Known to have been unusually heavy in 27 cases —not an unusually high proportion in cases limited to the hospital class of patient. Five cases found in which the work was very light, and neither rheumatism nor syphilis had occurred.

Physical Signs.

The physical signs are as follows :—

Tremor.—Striking rarity of those fine tremors of hands and tongue so constantly seen in the effort syndrome cases. In seven cases tremor of hands was well marked, but all seven patients were obviously and seriously ill. In only one case was tremor of the neurasthenic type seen.

Pallor.—Noticed in 30 cases, slight in eight, very striking in six.

Clubbing.—Definite clubbing of fingers in ten cases, in none of which was any sign of a congenital lesion, but in four cases there were other signs of an active infection.

Petechiæ.—Much difficulty was encountered in determining the occurrence of petechiæ. In many cases, originally seen in the out-patient department, and later taken into the wards for observation, such petechial spots as were found around the neck, lateral aspects of thorax and abdomen, outer side of thighs, &c., entirely disappeared after a week in hospital. In only four cases were petechiæ satisfactorily demonstrated ; these all had an infective endocarditis and are already dead.

Vessels.—The apparently enlarged, tortuous, pulsating temporal artery was observed in 23 cases ; the violently pulsating neck vessels absent in only five cases. Capillary pulsation found 36 times.

Area of cardiac dullness.—This area, as determined by light percussion, was found materially enlarged in all but four cases, in which four there was other evidence that the aortic defect was only slight.

Position of heart apex beat.—Found to be as follows :— Aortic incompetence alone : fifth space, 11 cases ; sixth space, 22 cases. Aortic incompetence with presystolic murmur : fifth space, 6 cases ; sixth space, 11 cases.

The degree to which the apex beat extended beyond the left nipple line varied considerably, in four cases reaching as far out as the anterior axillary line. The character of the apex beat was normal in nine cases, in seven of which the aortic second sound was audible in the neck. The beat was powerful and heaving in 38 cases, but wavy and extending over several intercostal spaces in three cases—one of which had ulcerative endocarditis, one is thought to have subacute endocarditis, and the third has active syphilis, very thick vessels, and a small heart.

Murmurs.—Only three cases were found in which no murmur was audible at the apex. In 16 cases a presystolic crescendo murmur was audible. The diastolic murmur was itself heard at the apex in 34 cases, and in 10 cases only a systolic murmur was heard there. At the aortic cartilage a to-and-fro murmur was heard in 33 cases ; in the remainder of the cases a diastolic murmur only was heard, among the latter the murmur difficult to hear was encountered. In 21 cases the second sound was audible at the root of the neck ; in the remainder it was inaudible. As above stated, a presystolic murmur was found 16 times, and of these 16 cases, 11 gave a clinical history of rheumatic affections.

Pulse.—Varied in frequency at rest from 60 to 120 beats per minute ; definitely collapsing in character in 35 cases.

Group 10.—Found in 2 abnormal natives, and 2 normal natives. A high-titre agglutinating serum prepared locally against a *B. pyocyaneus* strain isolated from blood of native S. (cf. blood cultures below) agglutinated fully to 1/610 (highest dilution used) with two strains from two different normal natives.

TABLE II.—*Showing Percentage Occurrence of Various Groups in the Stools Examined.*

Group.	In abnormal natives (total 26).	In normal natives (total 38).	In abnormal Europeans (total 12).	In abnormal Indians (total 1).
1	7·6	26·3	16·6	—
2	26·9	52·6	24·9	—
3	7·6	5·2	—	—
4	22·8	2·6	24·9	—

7	11·4	2·6	8·3	—
8	11·4	7·8	8·3	—
9	5·2	3·8	8·3	—
10	5·2	3·8	8·3	—

Blood Cultures.

A small number of blood cultures were performed in connexion with the above investigations. On three occasions Gram-negative bacilli were recovered —twice from native S., whose disease resembled mild typhoid, and once from European W., who suffered from a low enteric-like fever lasting three weeks without any characteristic bowel symptoms.

Technique.—Blood was drawn from a convenient vein in the arm by means of a sterile all-glass syringe. At first the citrated blood was added to broth—with or without the trypsin suggested by Douglas[3]—and to sterile ox bile. Latterly the clot method was employed. The blood was allowed to clot in the test-tube, the serum removed, and the clot carefully washed with sterile saline. The washed clot was subsequently broken up with a sterile glass rod, and the fragments added to 2 per cent. sodium taurocholate in distilled water. All the three positive results were obtained by the clot method.

Clinical Description of Cases.

(*a*) *Native S.* (male). The following description was kindly supplied by Dr. W. L. Webb, medical officer, Kampala.

"S. was admitted to the gaol hospital on Oct. 16th, 1920, apparently on the first day he had felt indisposed enough to claim exemption from work. Temperature on admission, 100° F., rising that evening to 103° F. Blood negative to malaria; tongue coated almost completely with white fur; no enlargement of spleen could be made out, no rash was seen; a tendency to diarrhœa during first ten days. Stools typical of typhoid throughout. Temperature reached normal on fourteenth day of disease. The man was weak, and lost weight during his illness, but during the whole time was mentally alert. S. was transferred from Masindi to Kampala gaol during January, 1920. During his stay in gaol he has performed ordinary prison duties, cultivation, wood and water carrying, &c. No previous illness is noted on his sick sheet."

The patient's serum on Oct. 18th, 1920, gave no agglutination with *B. typhosus*. The available charts showed a gradual rise to 105° during the first nine days followed by a return to normal during the next four days. Unfortunately the temperature chart covering the date of the second positive blood culture is not available at the moment of writing, but to the best of my recollection a slight secondary rise occurred for a few days. At all events no marked rise occurred in connexion with the presence in the blood of *B. pyocyaneus*, a state of affairs in striking contrast to the usual course pursued in pyocyaneus bacillæmia in whites.

(*b*) *European W.* (female). The patient had been indisposed for a few days before admission. Bowels never loose throughout the illness; indeed, there was a tendency towards constipation. Tongue furred. Slight general tenderness to pressure on abdomen. Headache and general malaise were the main symptoms complained of, and the patient remained bright and comparatively cheerful throughout her stay in hospital. No rash was seen at any time. Patient's serum was tested on Jan. 14th, 1921, against *B. typhosus*, *B. para A* and *B*, *para C*, *M. melitensis* and *para-melitensis*, and *B. proteus* with negative results. On Feb. 16th, 1921, the serum was again negative to *B. typhosus*, *para A* and *B*, from 1/20 to 1/320 dilution. Patient ultimately discharged from hospital in excellent health. For the first 18 days after admission the temperature remained between 99° and 101°, on only four occasions passing 101° by a point or two. On the 11 following days the evening temperature reached 99°.

Description of the Organisms and their Serological Reactions.

(*a*) *From native S.* First positive blood culture performed on Oct. 21st, 1920. On the MacConkey plates inoculated from the 2 per cent. sodium taurocholate tube, and also from a glucose broth tube to which another portion of the clot had been added, a bacillus, No. 190f, was isolated in pure culture. This bacillus gave all the reactions of Group 2. The growth on agar tended to become sticky after a few days, and a pellicle was often noticeable in the sugar tubes. A second positive blood culture was obtained from native S. on Nov. 7th, 1921, when organism 190m, giving the reactions of *B. pyocyaneus*, was isolated in pure culture.

Serological Tests.—(1) *With organism No. 190f.* A rabbit was prepared against No. 190f, and a high titre serum was obtained which we will call serum 190f. On Oct. 29th and Nov. 7th, 1920, the patient's serum gave no agglutination with No. 190f from 1/20 upwards. Bacillus 190f was not agglutinated in any dilution, from 1/20 upwards, with any of the following serums: B. and W. *typhosus para A*, *para B*, a high titre serum prepared against the organism isolated from European W. (cf. infra), and the serum of European W. Serum 190f gave no agglutination from 1/20 upwards with organisms of Group 2 isolated from the stools of ten different natives, normal and abnormal; but it agglutinated completely to 1/320 (highest dilution tried) No. 236d, a member of Group 2, which was isolated from the stool of European W.

(2) *With organism No. 190m.* The patient's serum gave no agglutination response with No. 190m a few days after its isolation. A rabbit was prepared against No. 190m and a high titre serum, which we will call serum 190m, was obtained. This serum 190m gave rapid and complete agglutination to 1/320 (highest dilution tried) with Nos. 115a and 143c, which were typical pyocyaneus strains isolated at different times from the stools of normal natives.

The case of native S. is of interest in that two different organisms were isolated from the patient's blood on different occasions. On each occasion the organism found was present in pure culture. On the day on which No. 190f was isolated, clot cultures were made from nine other natives in the same ward, all of whom were suffering from acute Flexner dysentery (cf. Group 4, Nos. 211–213 of Table I.). The same technique was employed for all the cases, a sodium taurocholate and a glucose broth tube receiving portions of the clot from each individual. In eight of the nine dysentery cases both tubes remained sterile. In the ninth case the glucose broth tube was contaminated with a Gram-positive motile bacillus, the bile-salt tube remaining negative. On several other occasions in which clot blood cultures were made, the tubes remained absolutely sterile. In view of these control experiments, together with the unlikelihood of *B. fæcalis alkaligenes* obtruding as a contamination during carefully conducted blood culture experiments, I consider that Cases S. and W. are genuine examples of an invasion of the blood by the organisms isolated.

(*b*) *From European W.*—Isolated on Jan. 14th, 1921, by adding broken up washed clot to 2 per cent. sodium taurocholate in distilled water. The organism appeared in pure culture, and gave the reactions of Group 2, save that it rapidly blackened lead acetate agar. Clot blood cultures performed on patient W. on two other occasions, within ten days of the isolation of bacillus "W.," proved sterile.

Serological Tests with Bacillus "W."—A high-titre rabbit serum was prepared against the organism. This serum gave no agglutination in any dilution from 1/20 upwards with any of ten strains of Group 2 isolated from ten different natives, normal and abnormal. With No. 232a (a Group 2 organism from the stool of a normal native) this serum gave complete and rapid agglutination up to 1/320 (highest dilution used). Bacillus No. 232a differs from bacillus W. by producing no blackening on lead acetate agar. The serum of patient W. gave no agglutination on two different days, from 1/20 dilution upwards, with either bacillus W. or No. 190f (from native S.), or with bacilli of Group 2 isolated from the stools of four different normal natives, one abnormal European, and the patient's own stool (No. 236d).

Organisms Isolated from the Stools of Patients S. and W.

(*a*) CASE S.—On Oct. 29th, 1920, bacillus No. 102 was present in considerable numbers in the stool, which was of pea-soup character. This organism conforms with Group 1, save that it appears to be non-motile, that milk is turned acid (this requires confirmation), and that neutral-red is turned pink. It was thought that this bacillus might be a typhosus strain with some of its characters masked, but no response was given with either a B. and W. *typhosus* only one a history of rheumatism. Of the 17 cases, 6 had a rheumatic history, 5 a positive W.R., and 5 arterio-sclerosis.

Conclusions.

The prognosis in aortic disease remains almost as difficult a problem to-day as it was years ago. Nevertheless modern methods do give invaluable help in certain cases. Pathological increase in the P.R. interval or the duration of the Q.R.S. complex yields information as to myocardial damage which could not be arrived at by other means or could only be guessed at without any definite proof—e.g., P.R. interval increase, four cases. two already dead. Inversion of T. in lead 2, four cases. one already dead. and two others seriously ill. But this matter of "looking for a sign" remains as unprofitable in this century as in any other; it is only by utilising every method of investigation, old as well as new, that a correct estimate is likely to be arrived at in these difficult cases.

Active infections.—The careful and repeated examination of the urine for red blood cells, the systematic search for petechiæ, enlargement of the spleen, pallor and clubbed fingers—as indicative of the subacute bacterial endocarditis described by Libman and by Horder—is perhaps the most important procedure in the whole clinical examination of the patients, and only to a less extent, because less frequent, in all cardiac cases.

Ætiology.—Arteriosclerosis and renal disease, long regarded as ætiological factors, also demand special investigation, more particularly as regards renal function and retinal hæmorrhages. The W.R. and X ray examination both give invaluable help, especially as regards the occurrence of aneurysm, which, although present, may give no signs or symptoms at all.

Correlation of findings.—The correlation of all the findings will probably point the way, and each factor follow the expected line; yet in a certain number of cases this will not be so, and explanation of the anomaly may be extremely difficult. Where the size of the heart does not appear to correspond to the degree of regurgitation, as judged by the collapsing character of the pulse, difference in systolic and diastolic pressures, presence or absence of aortic second sound at the root of the neck, and the presence of L.S.P. in the electrocardiogram, the possibility of an adherent mediastino-pericarditis must be borne in mind; it was thought to be a possibility in only one case of this series. Of the 40 cases fully investigated, all the facts arrived at followed the expected line in 31, but in 9 cases the findings did not correspond in some particular. Of these nine cases 3 are already dead, 1 has an active endocarditis, 1 probably an adherent pericardium, and the other 4 cannot be at present explained. Those factors which herald a lethal result have already been sufficiently insisted upon. but it would seem that cases which show a want of correspondence in all the findings of a routine examination should also be regarded as of serious outlook.

I wish to thank Dr. Arnold Renshaw, pathologist, and Dr. J. M. W. Morison, radiologist, for much help in routine work, and the Pathological Department of the University of Manchester, whose generous grant made this work possible.

ROYAL SUSSEX COUNTY HOSPITAL, BRIGHTON.—In the last two decades great extensions have been made to this hospital. but circumstances have till now prevented a corresponding extension in the accommodation for nurses. The original nurses' home could provide lodging for 43 of the nursing staff; now the staff numbers 78. As far back as 1907 the matter became pressing, the provision of accommodation in rented houses involving discomfort to the staff in addition to being a costly procedure. In 1912 the governors had plans prepared for an extension of the original nurses' home; a special appeal for funds was made early in 1911, but the project had then to be abandoned, and it remained in abeyance until 1919, when a legacy of over £20,000 was left by Miss Walker. This legacy was treated as capital, and at a cost of £23,000 accommodation has now been found for 88 nurses. The extension to the nurses' home was opened by Princess Mary on Nov. 22nd, on the occasion of her first visit to Brighton in an official capacity. She also presented badges to nurses.

ON THE
NON-LACTOSE-FERMENTING BACILLI
IN THE STOOLS OF HEALTHY AND UNHEALTHY UGANDA NATIVES.
(*Preliminary Observations.*)

BY H. LYNDHURST DUKE, *O.B.E.*, M.D.,
D.T.M. & H. CAMB.,
BACTERIOLOGIST, UGANDA PROTECTORATE.

THE establishment of a laboratory in a country where the bacteriological aspects of disease have hitherto received practically no attention entails a great deal of preliminary work in order to arrive at a proper appreciation of the limits of normal health for the community. In Uganda we have to deal with a mixed population of Europeans, Asiatics, and natives, many of whom are strangers in the land and only partially adapted to their environment. The native community includes members of many different tribes, accustomed to different dietetic and climatic conditions, and about whose nosology relatively little is known. In the Uganda Laboratory Report for 1920 a number of Arneth counts were published, which were made with the object of revealing the limits within which variation is compatible with normal health in the various communities. From the little that has been done in this direction it is already clear that considerable care must be used in basing conclusions on this test. The investigations recorded below deal with the non-lactose-fermenting Gram-negative bacilli present in the fæces of healthy and abnormal inhabitants of Uganda—coloured and white. Attention has been confined to non-lactose fermenters, because most of the recognised pathogenic intestinal organisms belong to this category. The work of Douglas and Colebrook and others for the Medical Research Committee has afforded a model upon which the inquiry was roughly moulded, and the results obtained are presented in the briefest manner possible in view of the paucity of the material examined and the relative incompleteness of the examination.

The observations here recorded represent the work of one session terminated by my departure on leave. During my absence the majority of the strains described below will be maintained on agar, to be re-examined when occasion offers. The small number of serological tests applied up to date is explained by the press of routine and other work on the limited laboratory staff. No absorption tests were possible owing to the absence of a suitable centrifuge, but it is hoped to overcome this difficulty next session. It was necessary also to dispense with pathogenicity tests, as the supply of animals was inadequate. The organisms isolated have been grouped provisionally according to the principal sugar reactions. It is realised that the sugar fermentation reactions of an organism do not constitute an infallible means of differentiating species, but they supply a convenient expedient in inquiry of this nature. At present Uganda is fortunate in being relatively free from enteric disease, but the knowledge that must accrue from an investigation of this nature will prove of value should a demand for a prophylactic vaccine arise in the future. It will be interesting to see whether the serological races indicated in some of the groups below will survive the test of absorption. The recognition of serological affinity among strains giving the reactions of Morgan's bacillus No. 1, and isolated in Uganda and Kenya Colony respectively, may prove of some significance in view of Pirie's observations on this organism in Nairobi.[1]

Technique.

A small portion of the stool was thoroughly emulsified in sterile distilled water in a test-tube, and after the emulsion had stood for some 15 minutes a loopful was spread on a MacConkey plate. Only one plate was used for each direct plating, and at times only half a plate. At the same time two or three loopfuls of the emulsion were inoculated into peptone-water tubes containing 0·4 and 0·6 c.cm. of a 1/10,000 solution of brilliant green per 10 c.cm. of medium

Balance of Calcium Metabolism.

In health, he said, the balance of calcium metabolism was controlled by the endocrine apparatus. The parathyroids, pars anterior of pituitary, medulla of suprarenal, with possibly the thymus gland, regulated absorption and fixation, while the gonads (ovary and testis) and possibly the thyroid, regulated excretion. In tetany, due to parathyroid insufficiency, the calcium content of the blood had been shown to be much reduced, while in acromegaly, due to hyperplasia of the pars anterior of the pituitary, there was increased deposit of fixed inorganic lime. The inactivity of the gonads during youth helped the growing child to keep and utilise lime, while the absence of ovarian secretion helped the pregnant woman to conserve lime salts for her child. Mr. Broderick had found that as the result of infectious fevers in children (with their concomitant overstimulation and final exhaustion of the endocrine glands) the saliva during convalescence was deficient in alkalinity and in calcium content. By the administration of suitable pluriglandular preparations a rapid recovery of alkalinity and normal calcium content could, in Mr. Broderick's opinion, be brought about. As a result of his researches into the alkalinity of the saliva, he had found that the alkaline index was higher in children than in adults, but the highest index occurred in old people who suffered from pyorrhœa. The alkaline index was generally low in ill-health and where progressive caries existed. It was his belief that the diminished alkalinity of the saliva which predisposed to caries was due to an upset in the balance of the endocrine glands.

The Antagonism of Pyorrhœa and Caries.

The endocrine glands, in the opinion of Mr. Broderick, were also responsible for the rate of utilising calcium ions. He had seen recently two pronounced cases of acromegaly where the teeth had been removed for pyorrhœa. Dentists knew that pyorrhœa and caries were antagonistic conditions, and that the former occurred with hard sound teeth that had withstood caries. In osteomalacia, where the reverse changes took place in the skeleton, the changes in the teeth had been carelessly reported on by medical men. Since bones harden or soften as the result of endocrine derangement: might not the same causal agents underlie the alteration in the consistency of the teeth?

The Bearing of Acidosis on Caries.

The important condition of acidosis had been defined by Sellard as "a diminution from any cause in the reserve supply of the alkaline bases in the blood and other tissues, ... the physico-chemical reaction of the blood remaining unchanged, except in extreme conditions." In the normal metabolism of foodstuffs there was a constant tendency towards the production of acids which were normally got rid of by the lungs as CO_2, by the kidneys in form of acid salts, by neutralisation with ammonia formed in metabolism of proteins, and lastly, by using up the body supply of alkaline salts. The first line of defence against acidosis lay in the carbonates and phosphates of the blood. As regards the carbonates, the reaction was expressed—$NaHCO_3 + HCl = NaCl + H_2O + CO_2$, the neutral salt (NaCl) being excreted by the kidneys, with the loss to the body of its alkaline base. Every acid molecule would thus rob the body of alkali but for the action of the alkaline sodium hydrogen phosphate in the blood, which when reacting with CO_2 reproduced $NaHCO_3$, e.g.:

$$Na_2HPO_4 + H_2O + CO_2 = NaH_2PO_4 + NaHCO_3.$$

Thus even in health acids formed within the body, or, taken in food, slowly acted as a drain on the alkali reserve of the blood which had constantly to be replenished. Calcium did not normally form an important element of this alkali reserve, although in acidosis a marked diminution of calcium took place in the blood serum, and if calcium salts were demanded for the mere vital purpose of overcoming acidosis they were no longer available for their primary purpose of hardening the skeleton and the teeth. There was clinical evidence in support of this. The demands of the body for alkali after the acidosis of acute fevers led to rapid tooth destruction often seen during and after convalescence.

There was a further point in the consideration of acidosis of special interest to dentists. Many dentists were obsessed by the idea that the large proportion of carbohydrate in the modern diet was largely responsible for the prevalence of caries. It must be remembered, however, that to cut down carbohydrates to a minimum was to tend to create acidosis. Mrs. May Mellanby, in her work upon vitamins, had shown that feeding on a diet deficient in vitamin A led to deterioration of the dental tissues, and Howe had produced caries in animals by similar means. McCarrison conclusively proved that food deficiencies had a definite action on the endocrine apparatus and hence arose the changes in the teeth.

Mr. Broderick's conclusions were as follows:—

1. So long as the enamel remains intact there can be no caries.
2. *Enamel in health progressively hardens as life proceeds.*
3. This hardening is due to a progressive laying down of lime salts, taken from the body store of ionic calcium.
4. *This body store is, in health, equivalent to the need* of the individual at the time, and is preserved by the endocrine apparatus, which is also the fixer of lime salts in the teeth.
5. If the endocrine apparatus is thrown out of balance in the direction of calcium starvation, this reserve store is diminished, and *fixation of lime salts in the teeth is interfered* with.
6. An upset in endocrine balance in childhood youth and pregnancy *will be in the direction of calcium starvation.*
7. Calcium starvation will lead to a diminished calcium index in the saliva, with a lessened alkalinity of that secretion, *thus directly promoting caries.*
8. Endocrine derangement, leading to a loss in balance towards calcium starvation, will tend to produce a condition *of acidosis by lessening the alkali reserve of the body*; in the compensation of this condition the calcium salts, together with other alkaline salts, will be utilised for acid neutralisation, *and therefore not be available for the hypercalcifying* the teeth.
9. If the acidosis be more severe, built-up and fixed *inorganic lime will be torn away from bones and teeth to* help build up this alkali reserve, and thus preserves life, lowering the resistance of the teeth to caries.
10. *That without this susceptibility to caries, exciting* causes such as food fermentation do not matter; but if immunity be removed hardly any reasonable care and *attention are sufficient to preserve the teeth entire.*
11. That endocrine derangement will account for all the conditions leading to dental caries, whether they be diet, *lack of vitamins, or altered salivary secretion.*

Mr. Broderick showed the skulls of three rabbits from the same litter. The first had been fed on a normal diet, while the diet of the second and third contained ovarian extract, and a mixture of extracts of thyroid, pituitary, and suprarenal glands respectively. It was noticed that the teeth of the rabbit fed on ovarian extract had thinner enamel than that of the one on normal diet, while the teeth of the rabbit fed on the mixture of gland extracts were larger, and the enamel was the more dense.

Discussion.

The PRESIDENT, in opening the discussion, suggested that much experimental work would be required to establish some of the introducer's deductions.

Prof. W. D. HALLIBURTON found much in the paper of a suggestive nature. It was now being widely realised that the health of the teeth did not depend entirely on the use of the tooth-brush. He felt that Mr. Broderick was right to attach much importance to our knowledge of calcium metabolism; but while a vast amount of work had been done on this subject, there was still very little certain knowledge of it. He thought, however, that just as when the functions of the heart and lungs were first discovered, every disease was ascribed to some derangement of these organs, so at the present time there was a tendency to explain everything by an upset of the endocrine organs.

No. 128 gave complete agglutination at 1/160, traces at 1/640, with the patient's serum, and complete agglutination at 1/80, traces at 1/160, with the serum of an adjoining dysentery case. A rabbit was prepared against No. 128, and its serum gave complete agglutination to 1/320 (highest employed) with the two above-named Flexner strains from the Lister Institute. Bacillus No. 185, isolated from a native with clinical typhoid whose serum agglutinated *B. typhosus* in high titre, differed from the other members of the group by producing acid and no gas in dulcite and in turning milk faintly acid. Indol test positive. Other strains from the same stool produced in addition acid in lactose. These organisms were examined repeatedly for motility, but on no occasion was genuine motility seen. Organisms with the characters of Groups 1 and 2 were found in the same stool.

Group 5.—Found in 4 abnormal natives. No. 77c was agglutinated up to 1/160 by the patient's serum, the particles being fine throughout the series. The others of the group were not affected by their host's serums from 1/20 upwards. Nos. 77c, 96d, 31a, and 25 gave no agglutination response with B. and W. Flexner and typhosus serums. A rabbit was prepared against No. 25, and the high-titre serum so obtained tested against the other three members of the group. Nos. 77c and 96d and 31a gave no response, but No. 31b gave complete agglutination at 1/320, and particles easily visible to the naked eye at 1/160 with this serum. No. 31 is interesting. When first isolated the strain showed no action on saccharose, but in six months' time certain colonies were found to ferment this sugar. This race, known as No. 31b, was also distinguished from No. 31a by agglutinating completely at 1/320 with the serum of a rabbit prepared against No. 25.

Group 6.—Found in 1 abnormal native, 1 normal native, and 4 abnormal Europeans. No. 50 agglutinated completely to 1/1280 with the patient's serum. An organism, No. 49a, similar in general reactions to No. 50, isolated from the urine of the same patient, also agglutinated to 1/1280 with patients' serum. Controls with normal human serum negative. None of the other members of the group were agglutinated by either the host's serum or by B. and W. para A, para B, and enteritidis serums, or with a locally prepared para C serum from 1/40 upwards.

Group 7.—Found in 3 abnormal natives, 1 normal native, and 1 abnormal European. Corresponds to Douglas's Group V.[4] The organisms of this group all gave negative results with B. and W. para A, para B, and enteritidis serums, and also with the host's serum, from 1/40 upwards.

Group 8.—Found in 3 abnormal natives, 3 normal natives, and 1 abnormal European. Corresponds to Douglas's Group X. No. 29a gave almost complete agglutination at 1/80, traces at 1/160, with B. and W. enteritidis serum. None of the other members of the group gave any response from 1/40 upwards with either the host's serum or with B. and W. para A, para B, or enteritidis serums.

Group 9.—Found in 1 abnormal native, 1 normal native, and 1 abnormal European. Corresponds to Douglas's Group IV. No organism of this group gave any response with either the patient's serum or a locally prepared para C serum, or with B. and W. para A, para B, and enteritidis serums.

the point of interest being that each uterine contraction made the fibroid harden and protrude, causing the patient extreme pain.

Dr. Marshall divided the cases into three classes: (A) Cases which might safely proceed to term. (B) Cases requiring operation, but suitable for myomectomy. (C) Cases requiring hystero-myomectomy. As to Class A it was doubtful if there was any justification for the induction of abortion, as so many apparently hopeless cases proceeded to term. Large fibroids which had almost occluded the pelvis occasionally rose with the growth of the uterus, aided no doubt later by the development of the lower uterine segment, and normal delivery followed. In the Class A cases the main complaints to be feared were pain and hæmorrhage. Rest, sedatives as indicated, and general treatment usually met these cases, which, if not improving, must be considered as included in Class B. The indications for myomectomy were torsion of a subserous fibroid with necrosis, prolapse, or impaction of a subserous fibroid in the pelvis, an anterior fibroid causing retroflexion likely to cause abortion or incarceration and excessive pain. The cases suitable for this line of treatment were of the subserous type. It was not advisable to remove an interstitial fibroid of any size during pregnancy, because of the attendant hæmorrhage, the weakening of the uterine wall, and the frequency of abortion following. In three cases he had performed this operation, two proceeding later to term, the third aborting on the third day. In Class C the fibroids were generally very extensive and patient had extreme pain. Rest and the usual methods did not ease her.

The majority of cases which went to term terminated spontaneously, but one had to be prepared to meet more than usually severe labour-pains, uterine inertia, and malpresentations, and in neglected cases rupture of uterus would follow. Dr. Marshall recalled one case in which a fibroid in the pouch of Douglas had to be pushed past the brim to permit delivery, and he felt that had this been impracticable a posterior colpotomy might have been done. The correct line of treatment was Cæsarean section, in cases of obstruction, provided the patient was otherwise in a state for this operation. In the case of a fibroid which might be removed later by myomectomy, it was best to perform that operation at a later date, but in the presence of extensive fibroids or possible infection Cæsarean hysterectomy was the ideal line of treatment. Under proper supervision craniotomy should never be required, and pulling a child past an obstructing fibroid with forceps was certainly to be condemned. Post-partum hæmorrhage, both primary and secondary, was apt to occur in a uterus the seat of submucous and subserous fibroids. The possibility of these complications should not be forgotten, and means to combat them should always be at hand and used promptly. A more serious danger was sepsis. Pressure or injury during parturition might lead to degeneration and subsequent sepsis, or the tumour might be injured during forceps delivery and later become infected. In conclusion, Dr. Marshall expressed his astonishment at the extraordinary shrinkage noted in uterine fibroids after a pregnancy.

Discussion.

Prof. J. M. MUNRO KERR congratulated Dr. Marshall on his interesting communication. In view of the great tolerance of uterus and patients to fibroids he almost felt inclined to look upon pregnancy, labour, and the puerperium as the complications. In the past year he had seen four cases in which hysterectomy had been contemplated, but two of these had been carried safely to full time, when the patients had living children by means of Cæsarean section. Fibroids were apt to degenerate during pregnancy owing to the altered metabolism, and Prof. Kerr advocated the practice of elimination with rest in all cases. In cases where only one tumour of several caused trouble, this could often be removed by myomectomy. This operation was a simple one in pregnancy; rupture of uterus rarely followed it, and cases were recorded in which operators had gone down as far as the decidua without disturbing the pregnancy.

Dr. W. D. MCFARLANE had seen many cases which had appeared hopeless go to term. He agreed that stimulation of the excretory organs was of great advantage. One case of interest was that of a patient who had a pregnant fibroid uterus impacted in the pelvis. Laparotomy was performed, the uterus lifted from the pelvis, and the woman proceeded to term and delivered herself normally. After delivery the tumour was so reduced in size as to be almost unappreciable.

Dr. J. LINDSAY spoke from his experience as a general practitioner, whose attitude was to give pregnancy the preference to fibroids. He had never seen abortion follow fibroids, and in cases where fibroids had been appreciated in early pregnancy he had not experienced any difficulty in delivery.

Dr. CRAIG had had examples of abortion and sterility resulting from fibroids. In one case he had found a small fibroid in the pouch of Douglas; at the second confinement difficulty was experienced, and at the third induction proved necessary. Growth continued and hysterectomy was ultimately required.

In reply Dr. MARSHALL expressed satisfaction at the importance laid on the medical treatment of fibroids. The pregnancy was the all-important thing, and effort must be directed towards its preservation. He felt disinclined to accept myomectomy with its attendant risks, and in cases where operation was unavoidable greatly preferred hysterectomy.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

A MEETING of this Society was held on Nov. 24th, Dr. GODFREY CARTER, the President, being in the chair, when Mr. W. W. KING opened a discussion on

The Treatment of Ante-partum Hæmorrhage.

From an analysis of various hospital reports, covering nearly 60,000 deliveries, he had estimated that the incidence of this complication of childbirth was 2·5 per cent. as opposed to the usual estimate of 0·2 per cent. Mr. King confined his remarks to that variety of ante-partum hæmorrhage which results from placenta prævia, and showed that on theoretical grounds hæmorrhage, shock, and sepsis should be the three great dangers which would threaten the life and health of the mother. Prematurity, hæmorrhage, and the direct results of treatment were the corresponding causes of fœtal death. In the 898 cases of placenta prævia analysed 7·6 per cent. of the mothers and 55·3 per cent. of the children lost their lives. The figures were identical with some published 20 years ago, and show that there has been no improvement in the results of treatment during these years. A study of the maternal mortality showed that 15·9 per cent. of the total deaths occurred in women who were admitted to hospital in so grave a condition that they died undelivered. Out of 58 patients who were delivered 15·7 per cent. died of hæmorrhage, 18·9 per cent. of septicæmia, and 51·7 per cent. of shock. Considering the nature of the disease it was surprising that hæmorrhage had caused so few of the deaths. This would appear to show that the methods in common use for the arrest of hæmorrhage were efficient at least in this respect. Most, if not all, of the deaths from septicæmia were the result of faulty technique and should therefore have been avoided. Tissue-trauma in the presence of hæmorrhage was the great cause of shock, and the need for the gentlest manipulation, and, above all, of avoiding rapid delivery, did not appear even yet to have been fully realised. More than half the total deaths were due to this cause, and, in the majority of cases, it was clear from the records that death had resulted from the too hasty extraction of the child. The other deaths were not of obstetrical importance, with the exception of one from rupture of the uterus. In serum or with a locally-prepared high-titre *typhosus* serum. On Oct. 29th, 1920, and on Nov. 7th, 1920, the patient's serum gave no agglutination from 1/20 upwards with No. 192.

(*b*) CASE W.—A large proportion of late-lactose-fermenters were always present in both the direct and brilliant green plates from this patient. On one occasion No. 236d was isolated in practically pure culture on a brilliant green plate. No. 236d shows the typical characters of Group 2, lead acetate agar not being blackened. On several occasions *the patient's serum showed no agglutination from* 1/20 upwards with 236d. As mentioned above, serum 190f gave complete agglutination with No. 236d in two hours at 37° up to 1/320 (highest dilution used).

Thus from the blood of two patients—one native and one European—organisms with the general reactions of *B. fæcalis alkaligenes* have been recovered. These two organisms are quite distinct serologically, and while one (W.) blackens lead acetate agar in 18 hours, the other (190f) does not. That this latter characteristic has, however, no deep significance is indicated by the fact that while serological tests indicate close affinity between organisms 232a (from stool of normal native) and bacillus W. (from blood of European W.), No. 232a does not blacken lead acetate agar.

Conclusion.

The observations recorded in this paper, limited though they are, show that organisms assignable to Groups 1 and 2 of Table I. are relatively common in the fæces of normal natives in Uganda. The recovery on two occasions of organisms of Group 2 from the blood of patients suffering from typhoid-like disease, but whose serums give no agglutination with typhoid or paratyphoid bacilli, indicates that organisms of the *B. fæcalis alkaligenes* type may play an important part in the production of enteric disease in Uganda. In the event of a prophylactic enteric vaccine being called for in the Protectorate this type of organism must be considered. The existence within the limits of Group 2 of races showing no serological relation to one another must also be borne in mind. The work of *Shearman*[6] *and Hirst*[7] *is interesting in this connexion.*

MANCHESTER EAR HOSPITAL.—The sixty-fourth annual report shows that 5690 new patients were treated, nearly the same number as last year; the in-patients numbered 512, and the operations 891. *Patients are sent* to this hospital from as far afield as Hereford and even the Isle of Man.

CARE OF THE MENTALLY DEFECTIVE.—The Central Association for the Care of the Mentally Defective announce special lectures and an exhibition to be held during the tenth annual conference of Educational Associations at University College, Gower-street, London, W.C., from Jan. 2nd to the 6th, 1922. On Monday, Jan. 2nd, at 5 P.M., Miss Lucy G. Fildes will lecture on the Training of Teachers for Mentally Defective *and Backward Children* and Special Methods of Teaching. On Jan. 4th, at 10 A.M., Miss K. L. Marsden will speak on the Organisation and Scope of Backward Classes, and on Jan. 5th, at 5 P.M., the Possibility of Coöperation between the School Medical Officer and the Teacher in the Training of Sub-Normal and Mentally Defective Children will be the subject of an address by Dr. G. A. Auden. Members of the Association are entitled to free admission to the conference. Tickets for all meetings (7s. 6d.), or for single meetings (1s.), will be on sale at the secretary's table during the conference.

ROYAL SOCIETY OF MEDICINE.

SECTION OF ODONTOLOGY.

A MEETING of this section of the Royal Society of Medicine was held on Nov. 28th, Mr. M. F. HOPSON, the President, being in the chair.

Mr. F. W. BRODERICK read a paper on

THE ENDOCRINE FACTOR IN THE PRODUCTION OF IMMUNITY AND SUSCEPTIBILITY OF THE TEETH TO CARIES.

He said that the ætiology of dental caries had not yet been thoroughly elucidated. W. D. Miller's theory would explain the onset, and Sim Wallace's conclusions would explain the prevalence of caries; but these theories, if true, made it difficult to understand why any teeth should remain sound at all. Mr. Broderick contended that there must be some other factor in question besides the affinity of lime salts for acids, since acids were invariably present in the mouth whatever precautions might be taken. He quoted E. C. Kirk as saying that the susceptibility to dental caries varied at different periods of life; youth was most susceptible, while during adult life a period of immunity commonly supervened. Pregnancy increased the susceptibility. Dental caries occurred in mouths which were well kept both by the use of the tooth-brush and the skill of the dentist. Mr. Broderick said that he had previously put forward the theory that the calcium-utilising power of the body was influenced by the secretions of the endocrine glands. If the enamel formed a complete covering for the tooth, caries could not take place; but if the enamel were removed from even a small area, the tooth was inevitably doomed, unless artificial measures were taken, except in the extraordinary condition of "arrested caries." Clinically there was a wide range of differences in the enamel, in colour, opacity, and hardness; and as a rule, a tooth long erupted was harder than one recently so, although analysis did not reveal any great difference in the lime content.

Calcium Content.

The calcium content of the body occurred in two forms: (i.) fixed in the tissues as inorganic salts, and (ii.) as part of the alkali reserve of the body. The calcium, which was not needed for building or repairing acted as an alkali, gave tone to muscle, helped to govern the function of the heart, and kept up the excitability of nerve tissue. Of the total lime salts ingested, much was excreted without change in the intestine, and part that did enter the blood stream was excreted in the urine, after having perhaps functioned within the body in the ionic form; it was lost for the purpose of tooth-hardening which Mr. Broderick believed was normally a continuous process. Fixation of the ionic calcium in the tooth was as necessary as its absorption from the intestine. It was useless to increase the quantity of calcium in the diet in treating either dental conditions or such diseases as rickets or osteomalacia. The quantity of calcium necessary *to keep the body* in health was extremely small.

Need of Lime Salts.

Mr. Broderick quoted experimental evidence to show that mere deficiency of lime would not explain the prevalence of dental caries.

The need of lime salts varied at different ages. During growth it must obviously be greater, and during adult life the balance between intake and output was more stable except in women whose calcium metabolism was liable to the rapid alterations of pregnancy and menstruation. During the period of decay the tendency became rather towards calcium saturation.

asphyxia with accumulation of CO_2 in the tissues as the result of impeded circulation, from imperfect fat-metabolism, from elimination by the kidneys of alkali in excess, from any renal defect which inhibits the elimination of acid sodium phosphate. The physiological changes brought about had been made the basis of methods for the diagnosis of acidosis and the estimation of its degree, but none of them were quite satisfactory. The estimation of CO_2 tension in the alveolar air of infants and young children was not an easy procedure. The apparatus required expert manipulation and was difficult to use in routine work in private and in hospital. True acidosis was associated with but not always due to the presence of acetone bodies, and the most common cause of it from the clinical point of view seemed to be the excess of sodium phosphate in the blood. It was the function of the kidney to excrete this substance, and it did so normally in considerable quantity. Failure in this excretion resulted in retention and consequently diminished alkalinity. In most infantile diseases there was an associated pyrexia and urinary secretion was diminished sometimes to the point of anuria. Renal function was often inactive even without the existence of true renal disease. Impaired renal function was of high importance as a factor in the production of acidosis; it was frequently associated with ketosis, but the latter was usually of lesser importance.

Reviews and Notices of Books.

DICTIONARY OF PRACTICAL MEDICINE.

Edited by Sir MALCOLM MORRIS, K.C.V.O., FREDERICK LANGMEAD, M.D., F.R.C.P., and GORDON M. HOLMES, C.M.G., C.B., M.D. Dub., F.R.C.P. In three volumes, containing in all 1796 pages. London: Cassell and Co., Ltd. 1921. £5 5*s*. complete.

THIS dictionary ranges over the whole gamut of medicine, surgery (with the exception of fractures, dislocations, and major operations), midwifery (not including labour), gynæcology, dermatology, clinical pathology and bacteriology, forensic medicine, public health, and anæsthetics—and the important task is accomplished in a work of three volumes. With such an ambitious scope it is clear that all subjects cannot be dealt with fully, and that the dictionary must not be compared with a series of standard text-books dealing with the individual subjects. To justify its existence it must, therefore, present in a handy form the essentials of knowledge contained in the text-books and journals, together with the personal views of the contributors.

As regards medicine, we can but postulate a hypothetical practitioner who seeks help when confronted with a patient showing slightly unusual symptoms, and try to estimate what help he would receive. One faced with an atypical cretin could not fail to find illumination from the illustrated note on cretinism, while the brief reminder of the symptoms of diverticulitis might well serve to clinch the diagnosis in an obscure case. The article on disseminated sclerosis is up to date, including modern conceptions of its ætiology, and in a disease whose early manifestations may be so varied the section on symptomatology should be of great use. In seeking information on less well-defined conditions the practitioner may be less well served. If consulted by a patient who has expectorated a fibrinous cast from his bronchi, he will find no reference to this somewhat obscure but important condition under the heading "bronchial" or "cast." From "fibrinous bronchitis" he will be directed by a cross-reference to "bronchitis"; in the article on this subject the only relevant allusion is that in cases of diphtheritic infection of the bronchi a fibrinous membrane may be formed in the large tubes, but this, of course, has nothing to do with true fibrinous bronchitis which may occur in acute or chronic varieties. Again, the practitioner may seek information on modern views of asthma, on the diagnosis of difficult cases by their sensibility to various cutaneous protein tests, and on treatment by means of desensitisation by antigens. These methods are sufficiently well recognised to merit mention in any modern account of asthma, but receive none here; moreover, asthma is regarded by some at least as a toxic idiopathy, not necessarily due to reflex vagal stimulation.

Medico-legal work often presents far more difficulty to the busy practitioner than does any problem in diagnosis or treatment. He may well feel at a loss how to proceed when suddenly called in to give evidence in a doubtful case of infanticide or of injury; these subjects are admirably dealt with, and the article on medical evidence should be of considerable help in the preparation of data for the court. Under the heading of malpraxis the reader will find a pregnant and topical warning as to the dangers to which he is liable from an action for damages brought by a dissatisfied patient. As to surgical subjects, but little space is wasted on descriptions of difficult operations which can only be performed by the specialist. Advice is clearly given that a case in certain stated circumstances should or should not be operated upon, and this alone is what the practitioner requires to know. A few special points are well brought out. The importance of complete nephrectomy in cases of tuberculosis localised to one kidney is emphasised. Although such a line of treatment is well recognised by specialists, it is still only too often believed by practitioners, and even by consulting physicians, that palliative treatment is satisfactory; thus valuable time is often lost and the disease may be allowed to progress until the second kidney is affected. An unusual but very helpful section is that dealing with enlargement of lymphatic glands; in one short article the diagnosis is clearly and carefully considered. Intestinal obstruction is a subject deserving of rather wider consideration. It is curious to note that although operation is advised in some cases of hyperpituitarism, no such form of treatment is even suggested where there is a deficiency in the function of this gland. Fröhlich's syndrome and cases of the Loraine type are often due to cysts which may be cured by operative treatment.

On the whole the articles dealing with obstetric and gynæcological affections are disappointing, though the accounts of pruritus vulvæ, puerperal insanity, radium therapy, and syphilis deserve mention as being specially illuminating. The omission of any consideration of labour leaves a noticeable gap which cannot but affect the completeness of the accounts of conditions of pregnancy and the puerperium. In the discussion of puerperal eclampsia insufficient stress is laid upon the modern methods used by the Rotunda school, and perhaps too much stress upon veratrum, a drug not much used in this country. The warning against operative interference and the undue performance of Cæsarean section in this condition is a wise one. The old-fashioned distinction between sapræmia and septicæmia is still maintained under the heading puerperal septicæmia. This distinction is quite out of date, since the former is now recognised to be a mild grade of the latter. Under the heading of sterility we are told that prostitutes are sterile because of sexual exhaustion; this is probably not so, since the woman is generally quite a passive agent and the sterility in most cases is due to pelvic disease. The description of the pathology of subinvolution of the uterus is somewhat defective. The account of fibroids of the uterus is ill-balanced, too much stress being laid upon red degeneration, and the operation of myomectomy, recommended for certain cases, is not as a matter of fact much practised. The prognosis given of the probable results of operative treatment of carcinoma of the uterus is unduly optimistic. Most gynæcologists at present get but poor results, and the modern

Dr. **Leonard Williams** thought people should ask themselves "What can we do to be saved from this deadly heritage of caries?" Dr. Harry Campbell had contended that if our children were fed as we feed our puppy dogs on material which compelled vigorous mastication, the natural development of the jaws would be ensured, and malposition and malnutrition of the teeth abolished with the consequent caries, pain, and pyorrhœa. Dr. Williams held that this was not quite sufficient. A vigorous calcium metabolism was also necessary, and for this normally acting endocrine glands were essential. And to ensure a good team of endocrine glands one had to begin with the child in utero. The mother must be fed on vitamins. Lime was necessary to the teeth and jaws; endocrines were necessary to the lime, and vitamins were necessary to the endocrines. When the child had erupted his teeth he must be taught to masticate vitaminous foods, so that not only would he develop his masseter muscles and mandible, but also he would have normally working endocrines. The pituitary gland was of especial interest to odontologists. The high-arched palate, and the undeveloped mandible, so often associated with adenoids, were a "function" of pituitary insufficiency. The child was usually bright and well developed, but the outside upper incisors were badly developed and the nails had no half-moons at their roots. Sometimes there was a vagary of pigmentation. For these undeveloped jaws dentists sometimes prescribed pituitary extract. He emphasised two points: the preparation of the whole gland should be prescribed in doses of 5–6 gr. three times daily; pituitary therapy was useless unless the child was fed on an intensive vitamin dietary.

Mr. **J. A. Woods** (Liverpool) said that he had seen a patient suffering from osteomalacia, and her teeth were exceptionally good. He had noticed that during pregnancy there was no very marked increase in caries, except where there had been neglect beforehand. He thought Mr. Broderick had laid too much stress on the importance of the enamel.

Mr. **J. G. Turner** said that Mr. Broderick appeared to try to establish two main points: (1) that diminished alkalinity of the saliva leads directly to dental caries; (2) that enamel after eruption of the tooth undergoes both increase and decrease of its lime salts. Dealing with the first point, Mr. Turner asked whether it was certain that saliva ever reached the sites of caries, which depended on the lodgement of sticky starchy and sugary food together with acid-forming germs. They were covered by mucus. Decay always began in the "stagnation areas," never on the well-rubbed areas, which showed that susceptibility to decay was particular to portions of each tooth, not general to the whole tooth. Thus saliva had practically no influence on dental caries. Other observers had failed to find increased susceptibility to caries in acute illness: the decay which became apparent during the 6–12 weeks of an illness began months before and was due to show itself at this time. Caries of the enamel was a slow process. Mr. Turner himself had estimated that the least time to perforate the enamel at the buccal gum edge (this was not the extreme edge of the enamel) was nine months, and at the abutment area two years. Such figures put out of court observations based upon the decay of illness or pregnancy. Mr. Turner said that it was difficult to prove that enamel underwent variation in its content of lime salts. If mucus was impervious to saliva this thesis fell to the ground at once. Clinically he did not know of such hardening. Hypoplasic enamel remained soft throughout life. He did not find that pyorrhœa and dental caries were mutually exclusive, they were commonly associated; so much so, that he called one form of dental caries "decay of pyorrhœa." Mr. Broderick quoted Dr. Kirk as saying that youth was the period of greatest susceptibility. In his (Mr. Turner's) experience there was a predisposition to decay throughout life. He attributed the relative immunity of adult life to the fact that fewer sweets were eaten, that there was some attempt at cleanliness, and that the removal of decayed teeth allowed drainage of the remainder.

Mr. **J. Howard Mummery** said that it was commonly taught that enamel was an inert or dead substance, as it did not appear to show any channels, yet the enamel of teeth was not absolutely impervious; it was susceptible to dyes. Many observers had shown extensive malformation in the enamel of the teeth even of apes. He himself had ground sections of teeth from a neolithic jaw, and even here there were numberless defects and fissures in the enamel.

Sir **Frank Colyer** said that Mr. Turner had already anticipated him in many observations he had intended to make. As regards the decay of pregnancy, when it occurred, he believed it was due to nothing more than the soft starchy foods commonly eaten by pregnant women. The caries of infancy he called "biscuit decay." Children were sent to bed after a meal of biscuit and milk, which resolved itself into an infective "biscuit poultice" around their teeth. Dr. Williams had said that we should feed our children as we feed our puppies. But even puppies were incorrectly fed on "pappy" food, and developed pyorrhœa in consequence. He said, as regards the formation of the jaws, here as elsewhere the shape of the bone depended on the forces acting upon it, and if the jaw were insufficiently used, it would be poorly developed. If endocrine derangement were responsible for dental caries why should 66 per cent. of 500 London horses have carious teeth, and why should hutch-fed rabbits also suffer from caries while the same animals in a wild state were practically immune? His brother, Dr. Stanley Colyer, had observed marked differences in the incidence of caries amongst three native tribes living in South Africa, which could only be accounted for by the very slight difference in the diet, since the tribes were ethnologically related and living under otherwise similar conditions. The tribe which included sugar in its diet was chiefly afflicted with caries!

Mr. **Broderick**, in reply, said he had come to learn and not to teach.

GLASGOW OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

A meeting of this Society was held on Nov. 16th in the Faculty Hall, Glasgow, when Dr. G. **Balfour Marshall** delivered his Presidential address on

Fibroids complicating Pregnancy, Labour, and Puerperium,

with illustrative cases. He said that since his undergraduate days great changes had come in the management of pregnancy, parturition, and the puerperium in cases complicated by uterine fibromyomata. Then it had been the teaching and the practice to induce abortion in many cases; with the development and comparative safety of laparotomy, Cæsarean section, and hysterectomy, the treatment was now revolutionised. Dr. Marshall pointed out that women suffering from fibroids were frequently sterile, and this was particularly true of the submucous and interstitial varieties of these growths. He quoted two cases in which women who had borne children subsequently became sterile owing to fibroids. Pregnancy could occur in cases of submucous and even polypoid fibroids, and although there was a tendency to abort, such pregnancies might proceed to term. Abortion and premature labour were sometimes due to fibroids, especially the submucous type. Dr. Marshall had met with abortion due to all varieties of fibroid, and three of which he described in detail. He described also the following case, illustrative of the production of premature labour by a sessile subserous fibroid.

Mrs. M., aged 25, one child. Complaint of abdominal pain and swelling. Examination revealed a seven months pregnancy complicated by a large subserous fibroid projecting from the anterior uterine wall at the level of the umbilicus. There was slight uterine hæmorrhage, and labour was just beginning. Patient delivered herself without difficulty, even if he does not undertake their treatment. In discussing various special conditions, the author has not hesitated to call in the aid of specialists with the result that there are authoritative chapters dealing with such subjects as tuberculosis, cutaneous lesions of the external genitalia, acidosis, X ray therapy, and radium treatment. The book is well illustrated, there is a good index, and a well-selected bibliography. Altogether the author is to be congratulated on the sound and clearly written text-book which should prove most useful to practitioners and students.

Menstruation and its Disorders.

By EMIL NOVAK, A.B., M.D., F.A.C.S., Instructor in Clinical Gynæcology, Johns Hopkins University. London and New York: D. Appleton and Co. With *40 illustrations.* 1921. Pp. 357. £1 1*s.*

As the author states in his preface, a great deal of new knowledge on the important subject of menstruation has been accumulated during the past 10 to 15 years, and our conception of the nature of this process has undergone a considerable change. This book is a most excellent monograph and contains a full account of all we know at the present time on this subject. In considering the relation between œstrus in the lower animals and menstruation in women the work of Heape is quoted with approval and his views are adopted. A good and well-illustrated account is given of the changes which occur in the mucous membrane of the uterus during menstruation. A full note is furnished upon Schroeder's description of the process, divided into the three stages of desquamation, proliferative and secretion, is given, and it is pointed out that if his work is confirmed it is a step forward in our knowledge of the relationship of ovulation and menstruation. Schroeder believes that, as a rule, ovulation takes place about the fifteenth day of the cycle, at the end of the proliferative stage, and further supports the old view that there is a complete loss of the superficial or functional layer of the endometrium followed by regeneration from the basal glands. The interesting question of the formation of the corpus luteum is fully discussed and illustrated. Dr. Novak inclines to the belief that the cells are of epithelial origin, but as he points out there is need for the study of larger numbers of early córpora lutea.

The old and the new views with regard to the causation of menstruation are passed in review, and the evidence in favour of the modern belief that the essential cause is the internal secretion of the ovary is well discussed. No doubt most readers would think that the non-coagulability of the menstrual blood was capable of a ready explanation, but that this is not so is evident from the fact that Dr. Novak is able to do no more than sum up the findings of those who have tried to explain this phenomenon. To show the thoroughness with which the author deals with the whole subject, we may mention that besides a good chapter on the clinical manifestations of menstruation, there are sections dealing with puberty, the hygiene of puberty, precocious menstruation, and non-menstrual genital hæmorrhages in the new-born; these are followed by three chapters dealing with the menopause and an interesting study of the relation of menstruation to ovulation. From the histological evidence, which seems the most trustworthy, there appears to be a definite relation between the two, and ovulation would seem to occur most commonly between the fifth and fourteenth day of the cycle. Amenorrhœa, dysmenorrhœa, and intermenstrual pain are fully considered, and there is also a useful chapter on hæmorrhage from the uterus, special importance being given to the functional variety. A very useful and practical chapter is the one dealing with the part played by the endocrine glands in association with the menses and the organotherapy of menstrual disorders. The final chapter on treatment by radium and X rays is contributed by Prof. Howard Kelly and Dr. C. F. Burnham. There is a full and complete index.

A good monograph, full of sound information and with excellent bibliographies.

LIFE AND TIMES OF AMBROISE PARÉ.

With a new translation of his Apology and an Account of his Journeys in Divers Places. By FRANCIS R. PACKARD, M.D. New York: Paul B. Hoeber. 1921. Pp. 297. $7.50.

GRANTED that it was worth while to write another book about Paré after Mr. Stephen Paget's work, to which Dr. Packard refers with praise, the book now before us is compiled as well as possible except for one or two slips. The illustrations are many and good, there are two maps of old Paris, and an admirable index is included. Thomas Johnson's translation of the Apology and the Journals is known to most men who study medical history, but the style is too archaic for some people. We note that both on the frontispiece and in the table of illustrations Johnson's name is mispelled as Johnston, an error which should be corrected. Another slip occurs in a footnote on p. 153, "The Low Bretons speak a Celtic patois very dissimilar to French as spoken in Paris." Breton is not a patois but a distinct language, akin to Welsh and still more to the now extinct Cornish language. The Apology was written in answer to the attack made on Paré's use of the ligature in amputations, by Etienne Gourmelen. It was a crushing answer, and in addition remarkable for the way in which Paré insists on the necessity for practical knowledge in surgery as apart from that obtained from books. Altogether Dr. Packard's book is good reading.

BIOLOGICAL CHEMISTRY.

By H. E. ROAF, M.D., D.Sc., M.R.C.S., L.R.C.P., Professor of Physiology at London Hospital Medical College, University of London. London: Methuen and Co., Ltd. 1921. With 47 diagrams. Pp. 216. 10*s.* 6*d.*

THE diagram of biological processes, which forms the frontispiece of this interesting book, shows the extreme points of the range of biological chemistry. The various intermediate stages are described succinctly in the text under Sections II. and III., entitled Anabolism and Catabolism. Section I., Chemical and Physical, is an outline of the organic and physical chemistry needed for an understanding of the subject. The abstract facts of these subjects are very difficult to make clear and there is no short cut to their thorough understanding. Though considerable space is devoted to this section, it is not really adequate to explain the elements of chemistry; the reader is expected to have some knowledge, and of this he will be reminded by study of this section.

The section on anabolism deals first with photosynthesis and contains a short account of F. F. Blackman's researches on the conditions affecting this change, such as intensity of illumination and quality of light, temperature and concentration of the substrate, carbon dioxide, and the mechanism of light absorption by the chlorophyll. Here is also given a brief account of the chemistry of chlorophyll and other pigments and their possible functions. Carbon dioxide is transformed through formaldehyde to carbohydrate; this occurs probably by reduction through formic acid, but only the suggestion that the first stage is carbon monoxide and hydrogen is here mentioned. Polymerisation of formaldehyde to a hexose is evidently the next stage, though cane sugar or starch is the end-product. Hexose appears to break down to lactic acid through pyruvic aldehyde; pyruvic acid may yield acetaldehyde from which fat may be formed by aldol condensation, as suggested by Raper. Fat synthesis may equally well take place by the union of acetaldehyde and pyruvic acid according to Smedley, though the stages are more complicated. The synthesis of amino-acids for building up proteins one other case this catastrophe was recorded, but the patient recovered. As to details of treatment, Mr. King advised palliative treatment in the interests of the premature child when the hæmorrhage was slight and the conditions suitable. With severe loss and the patient not in labour Cæsarean section was generally the best treatment. In cases in which the patient was in labour the Champetier de Ribes bag should be used in the interests of all living and viable children. Version should only be used for the dead and non-viable. Rupture of the membranes was only safe when the hæmorrhage was slight and the os at least half dilated. By adopting palliative treatment in suitable cases under proper conditions, by Cæsarean section and by the use of the Champetier de Ribes bag, it should be possible to reduce considerably the enormous fœtal mortality of placenta prævia. The maternal death-rate would be reduced by early treatment, careful asepsis, gentle manipulation, and slow delivery. Morphia and intravenous glucose were advocated in the prevention and treatment of shock. Strychnine was useless and pituitary extract dangerous.

Discussion.

The PRESIDENT said that his practice had always been to effect delivery as soon as possible, irrespective of the life of the child.—Mr. P. E. BARBER stated that in his experience version was the most satisfactory method of treatment. He asked what evidence there was that patients died of shock. He thought that hæmorrhage was the most common cause of death.—Prof. M. H. PHILLIPS, while agreeing upon the whole with the main propositions of the paper, thought that Cæsarean section should be more commonly performed for placenta prævia. He emphasised the danger of rapid delivery and of even slight post-partum hæmorrhage.—Mr. J. CHISHOLM related his conversion from rapid delivery to the saner method of slow extraction.

MANCHESTER MEDICAL SOCIETY.

A SPECIAL meeting of this Society was held on Nov. 23rd in conjunction with the members of the Liverpool Medical Institution in the Medical Society's Reading Room, University of Manchester. After the meeting the visitors were entertained to dinner by the members of the Manchester Medical Society. Dr. T. A. GOODFELLOW, President of the Manchester Medical Society, was in the chair.

Dr. R. J. M. BUCHANAN read a paper on

Points of Clinical Interest in the Diagnosis of Abdominal Diseases.

He emphasised the importance of definite pain as a sign of organic disease. He considered the terms "neuritic, "neurosis," and so forth in relation to abdominal disease as mostly wrong and certainly unsafe. So-called functional disease was the last to be sought for. Dr. Buchanan drew attention to abdominal pain caused by disease in the thorax—e.g., empyema, pulmonary syphilis, pericarditis, and spinal diseases—and to pleuritic effusion as an early herald of malignant disease in the abdomen. He thought that too little attention had been paid to careful auscultation of the abdomen, especially in localising peritonitis, and pointed out the value of light auscultation of the abdominal aorta for a bruit which he found present in pathological conditions in which the aorta is pressed upon, especially malignant disease. Dr. Buchanan suggested that this physical sign might be tested as occasion arose. He considered that delay in recuperation of the blood after hæmatemesis favoured a diagnosis of malignant disease. Profound anæmia often accompanied malignant disease of the cæcum. Dr. Buchanan emphasised the prevalence of venous thrombosis in malignant disease, and said that in any case of thrombosis the viscera should be examined. He spoke also of the exacerbation of symptoms with pyrexia noticeable in cases of leaking gastric and duodenal ulcer. Dr. Buchanan advocated that all cases in which X rays are used a complete "watch through" should be done. He pointed out the ease with which disease of the appendix could be revealed even to the demonstration of concretions, and illustrated this with lantern-slides. In such cases the cæcum was often distended, a Jackson's membrane present, and plication called for. Dr. Buchanan drew attention to the tender spots on the back in the region of the suprarenals in Addison's disease. His address was illustrated with water-colour drawings, radiographs, and lantern-slides.

Mr. G. P. NEWBOLT read a paper upon the

Diagnosis and Treatment of Carcinoma of the Large Intestine,

based upon 60 cases upon which he had operated. Of these 26 occurred in the sigmoid colon, 11 in the splenic flexure, 11 in the cæcum, 8 in the hepatic flexure, and 4 in the transverse colon. Out of 33 resections done up to 1917, 12 patients were alive at present. Sigmoid and splenic growths were, he thought, most favourable. He emphasised the importance of an early diagnosis in these cases if a successful result was to be obtained, pointing out the difficulty in diagnosis where the growth was small. Radiology had done a good deal in helping the exact location of some of these growths. He considered that a three-stage operation of cæcostomy, followed by excision of the growth with direct union, and later by a closure of the cæcostomy, was the ideal operation in the absence of obstruction. Paul's operation was the best in cases where obstruction was present. Cæcostomy should be done in patients who were very ill in consequence of acute obstruction. As 37 out of the 60 growths were situated in the sigmoid and splenic regions Mr. Newbolt advocated incision on that side in cases in which the situation of the growth had not been exactly diagnosed. Where obstruction existed he advocated exploration from the right side with the view of localising the growth, and then a cæcostomy, with free removal of the growth later when the intestines were empty. He suggested that the median incision was rarely necessary.

Dr. MURRAY BLIGH read a note on

Ketosis in Children,

in which he referred to the lack of practical assistance in the diagnosis of the condition and in the estimation of its degree. He considered there was urgent need of means to measure precisely the extent of acidosis in children. He referred to the practice of limiting the amount of food or of actually starving children immediately before operation and to the tendency of the anæsthetic, whether ether or chloroform, to convert a relatively mild ketosis into a severe intoxication. The custom of postponing operations because the tested urine showed the presence of acetone, the saturation of the child with bicarbonate of soda, and the infliction of a second period of starvation was based on unsound knowledge. The qualitative test for acetone indicated nothing more than that acetone, diacetic acid, and oxybutyric were present in the blood and were being eliminated in the urine. The presence of acetone in the urine of children was misleading as evidence of depletion of alkali reserve in the blood. It suggested the possibility of dangers which did not exist, and it led to uncontrolled treatment with alkalies. Dr. Bligh recalled the experiments of Prof. Haldane and his co-workers in which the eating of large quantities of alkali led to a state of alkalosis as evidenced by diuresis, increased alveolar CO_2, and diminution in the ammonia in the urine, but the appearance also of acid bodies in the urine. Acidosis occurred without acetonuria and also occasionally along with acetonuria when there was no relationship between the two conditions. The causes of acidosis were multiple. Physiologically it was a diminution below certain limits in the alkalinity of blood plasma. Clinically such a condition might result from bacterial infection, from fermentation and its resultant lactic acid production; from internal and the whole forms an attractive volume. The series is undoubtedly of value as a means of rapid reference to recent publications, and the practitioner is enabled to purchase separately the volumes dealing with subjects of especial interest to him.

LECTURES ON THE SURGERY OF THE STOMACH AND DUODENUM.

By JAMES SHERREN, C.B.E., F.R.C.S., Surgeon to the London Hospital; Member of the Council and Court of Examiners, Royal College of Surgeons of England; Examiner in Surgery, University of London. London: H. K. Lewis and Co., Ltd. 1921. Pp. 99. *4s. 6d.*

IN this book Mr. Sherren has published a series of lectures given by him to the students of the London Hospital. The diseases dealt with are gastric and duodenal ulcers, stenosis of the pylorus, and carcinoma of the stomach. The ætiology, symptomatology, and treatment of the simple ulcer is discussed fully. Around the subject of the chronic ulcer there has raged a controversy which cannot yet be said to have died down. Without entering into the merits of conflicting theories or methods, Mr. Sherren gives us his own views and methods of investigation and treatment, built upon a large experience. The book is a plea for more accurate clinical observation, for whereas test-meals and X rays may be of assistance, they are often misleading. The clue to a correct diagnosis lies in a review of the clinical aspects of the case, and the clue to success in treatment is in an early and exact diagnosis. In this book will be found much valuable help for those who have to deal with these difficult conditions.

OPERATIVE DENTAL SURGERY.

By J. B. PARFITT, L.R.C.P., M.R.C.S., L.D.S., Dental Surgeon and Lecturer on Operative Dental Surgery at the Dental School of Guy's Hospital. London: Edward Arnold and Co. 1921. With 108 illustrations. Pp. 319. *21s.*

Dr. Parfitt interprets his title in a somewhat limited sense, for he omits those proceedings of the dental surgeon which may be classed as minor surgical operations; for instance, the extraction of teeth is discussed only as regards the mechanical principles and not from the purely surgical aspect, and the reader will therefore find no detailed account of how best to remove teeth and no helpful suggestions for negotiating difficult teeth, such as the misplaced lower third molar. Perhaps in future editions the author may see his way to include an account of this side of operative dentistry, and so add to the value of what is undoubtedly a very useful work.

This book deals mainly with the methods of filling and crowning teeth, but there are also useful chapters on scaling, ionic medication, and the management of children, written in a concise yet clear way, so that we gain the impression that we are receiving the results of experience gained in practice and teaching. During recent years much attention has been drawn to the question of pulpless teeth, and many ailments have been attributed to the presence of such teeth in the mouth. The reader naturally turns with interest to see what are the author's views upon this subject. He deals with it in a broad-minded way; he shows the difficulties that are encountered in filling root canals, and points out that the safety and usefulness of such teeth depend entirely on the presence or absence of infection. He shows clearly, too, that it is impossible to remove all the pulp tissue from many teeth, but considers that if such tissue as is left is kept sterile during the operation on the pulp the patient's own natural or acquired immunity is very likely able to keep it permanently sterile. As regards septic teeth, he is of the opinion that such can be rendered sterile, and for this purpose he advocates the use of tricresol with 10 per cent. of paraform.

This book should be extremely useful to anyone engaged in the practice of dental surgery.

JOURNALS.

IN the JOURNAL OF THE R.A.M.C. for November Dr. H. M. Woodcock gives the first part of an article on *hæmatophagy*, a function of the large mononuclears, by which they absorb other blood elements when outworn. They digest these elements, and then portions of their pseudopodia become abstricted, and so blood platelets are formed. The article is well illustrated.—Major N. V. Lothian continues his historical investigation of the soldier's load, telling us that the Earl of Leicester (ca. 1560), whose armour is in the Tower, rode over 25 stone, which accounts for the heavy type of the knight's horses. He again remarks on the large number of non-combatant attendants who accompanied the heavily armed soldiers, as was evidenced at Bannockburn, when their charge over the "Gillies' Hill" appeared as the advance of a new army, and decided the fate of that historic day.—Captain W. D. Beamish believes he prevented an epidemic of influenza at Kasauli by volatilising iodine over a small spirit lamp in the barrack-rooms, and avoided having to close a school at Sanawar by similarly treating the class-rooms. The cost was half a rupee a day. His reports are certainly interesting.—Major J. E. H. Gatt observed an outbreak of mumps in a group of 400 Mahomedans, while 400 Hindus alongside entirely escaped, because the Mahomedans feed themselves with their hands out of a common dish, while the Hindus cook and eat, each by himself.—Lieut.-Colonel Langford Lloyd pleads for a peep-sight, one-tenth of an inch in diameter, as backsight for the service rifle, and decentred glasses for rifle shooting.—Major E. H. Myles finds that castor oil applied externally is the best treatment for vaccinia, and Sir L. Gubbins, formerly Director-General, wishes physical training to be continued throughout the soldier's service, and notes what fine men for the service the London carmen are, in part as the result of their continually working in the open air.

Reports and Analytical Records.

BIOLOGICALS: TESTS AND REMEDIES.

(BURROUGHS WELLCOME AND CO., SNOW HILL BLDGS., E.C. 1.)

Diphtheria Toxin for Schick Reaction.—This firm is now issuing phials of the diluted toxin ready for use in the Schick reaction. This test is performed by injecting intracutaneously in the arm 0·2 c.cm. diphtheria toxin diluted in saline to approximately 1 c.cm., an amount representing 1/50 minimum lethal dose for a guinea-pig. A phial for control test containing an equivalent amount of heated toxin is supplied. The test is based upon the fact that man normally possesses sufficient diphtheria antitoxin in his blood to neutralise this small amount of toxin injected. In such event a negative result is obtained and the patient is said to be immune. In some cases, however, this small amount of natural antitoxin is absent and the injected toxin gives a pink flushed area in the skin from half to one inch or more in diameter with a smaller deep red centre. This positive reaction signifies lack of immunity. The control test made with heated toxin in the other arm should, of course, show no reaction. Many thousands of diphtheria contacts examined in this way show that it is possible to separate immune from non-immune persons. An annotation on this test with references to recent literature appeared in THE LANCET, 1921, i., 1317. A previous test toxin issued was put up with 0·5 per cent. phenol and could not safely be kept for more than a fortnight.

Diphtheria Toxin-Antitoxin Mixture for Active Immunisation.—We have also received from the same firm samples of their diphtheria prophylactic toxin-antitoxin mixture. This mixture is stated to contain in 1 c.cm. a small amount of diphtheria toxin to which has been added just sufficient antitoxin to neutralise tendency to combine radium or X rays with operation is the outcome of dissatisfaction with present methods. Three subjects typical of those about which the practitioner often seeks in vain for information are infant feeding, examination for life insurance, and the preparation for, and the after-treatment of, operations. All of these are admirably presented.

Our selection for special praise or blame of certain individual sections of a well-planned work must not be allowed to give the impression that the volumes lack balance. The proportion of space and importance allotted to each subject is well maintained. There are numerous plates and figures illustrating the text, and some of the coloured plates are excellent. The contributors to the work are numerous and distinguished, and though all the articles may not reach the same high standard, most of them are complete, concise, and up to date, and the dictionary thus deserves a place in the library of every practitioner.

SEXUOLOGY.

Sexual Life of Primitive People. By H. FEHLINGER. Translated by S. HERBERT, M.D., and Mrs. HERBERT. London: A. and C. Black. 1921. Pp. 133. 6*s*.

Sex: For Parents and Teachers. By W. L. STOWELL, M.D. New York: The Macmillan Company. 1921. Pp. 204. 17*s*.

As is now acknowledged, the practice of politics has a good deal to learn from science, especially perhaps from medical science. Nowhere, surely, is there a more obvious lesson than the sexuological one, both at home and abroad. That peoples groaning under the evils of venereal disease and prostitution should seek to impose, more or less forcibly, their own practice in sexual matters upon other peoples practically free from the said evils, is an anomaly that will divert at any rate the Muse of History. Dr. Herbert has done good work in translating—capably enough—this well-documented but succinct account of the sex life of savages. We see again the peculiar character of ethnology—namely, the difficulty in making generalisations. "It is a mistake," says Fehlinger, "to assume hastily that customs among primitive people that appear strange to us must therefore be ancient and be relics of a primitive state. Every primitive race has a long history behind it, and it is not likely that it has remained static all the time." However, with physical characteristics we are on surer ground than with social culture; and in the author's account of the very late appearance of sexual secondary characters in a Melanesian tribe it may be permissible to see evidence of an approximation on their part to the primitive bisexuality. This is an exact and scientific work, which may be recommended as a source of information.

Dr. Stowell's is one of the countless popular expositions and recommendations of sexual enlightenment. It differs from them in general by being illustrated. Several of the plates are unnecessary—e.g., of a sow suckling a litter, especially as the animal is not, as stated, a Berkshire, but of the variety known as Large White. The work is orderly in arrangement, but poor and somewhat naïve in style. Parents and teachers may, however, find much helpful matter here, and their charges may in after years have cause to thank them for consulting the worthy and chatty pages of this book.

THE ORGANS OF INTERNAL SECRETION.

Their Diseases and Therapeutic Application. Third edition. By IVO GEIKIE COBB, M.D., M.R.C.S. London: Baillière, Tindall and Cox. 1921. Pp. 352. 10*s*. 6*d*.

Dr. Cobb's book on the organs of internal secretion was originally published in 1916, and a third edition is evidence of a favourable reception.

In the present volume two chapters have been added, one dealing with the inter-relationship of the ductless glands and the nervous system, and another in which some practical points on hormone-therapy are discussed. The book is intended for the general practitioner, and in this it fulfils its purpose very well, for Dr. Cobb avoids as far as possible the discussion of unproved theories, preferring to confine himself to such things as he has himself tested in practice or have been approved by men of large authority on the subject. The literature of endocrinology is now becoming voluminous, and too many authorities are being led by their enthusiasm into making exaggerated claims for their special methods of gland therapy. Dr. Cobb avoids these exaggerations; and is properly cautious in his presentation of the opinions of others where these have not been sufficiently corroborated. The book presents the main facts of our knowledge of the ductless glands in such a form as will prove of great value to the general practitioner.

Dr. Cobb devotes fully a quarter of his book to the thyroid gland and its disorders. His treatment of this subject is on the whole adequate, but his list of the minor thyroidal deficiencies might be extended. Both the suprarenal and pituitary glands receive somewhat less attention than they deserve; the physiological action of adrenalin on the circulation might with advantage be discussed in greater detail and the importance of minute doses in asthma pointed out. Dr. Cobb gives a very minor place to anterior pituitary, for he considers the action of the pituitary gland depends almost entirely on the active principle of the posterior lobe. This will not be admitted by all endocrinologists, for extracts of the anterior lobe have an extensive therapeutic application, both in the disorders of the young and in the degenerative changes of old age. More might be made also of the use of corpus luteum in treatment. These, however, are minor criticisms, and are not intended to detract from the value of the book, which admirably serves the purposes for which it is intended.

GYNÆCOLOGY.

By BROOKE M. ANSPACH, M.D., Associate in Gynæcology, University of Pennsylvania. With an introduction by JOHN G. CLARK. London and Philadelphia: J. B. Lippincott Company. With 562 illustrations. Pp. 752. 42*s*.

IN Dr. Clark's introduction this text-book is described as one of a type in which the author selects his literary references with great care and, combining these with the observation gathered from his mature experience, constructs a well-balanced text-book. It would seem that this is not undue praise, and the author is to be congratulated on the production of a well-written and comprehensive work. Considerable stress is laid upon the important facts in embryology, anatomy, and physiology, which should be known to the student when he begins the study of the diseases of women, and the chapter on embryology is well and copiously illustrated. A section dealing with developmental anomalies follows naturally, and then a good account of the anatomy and physiology of the pelvic organs. The chapters dealing with physical examination are well arranged, and the details of the investigation of the urinary tract are given more fully than is usual in a work of this kind. Particular diseases of the various parts of the genital tract are next dealt with in detail. In the chapter on diseases of the endometrium and myometrium there are some good illustrations of sections of the uterine wall treated with Weigert's stain. The chapter dealing with the hygiene of adolescence and the relation of neuroses to pelvic diseases is especially illuminating; and an important one from the point of view of everyday practice is that on backache, for the author describes very clearly the part played by status in the production of backache in women. Perhaps more space is devoted to the diseases of the urinary tract and of the anus and rectum than is usual in English text-books of gynæcology, but, after all, a knowledge of these affections is essential to the gynæcologist

THE LANCET.

LONDON: SATURDAY, DECEMBER 10, 1921.

Old and New Methods of Diphtheria Prevention.

THE report on diphtheria, made to the Ministry of Health by Dr. S. MONCKTON COPEMAN, published last week, should give an impetus to the greater use in this country both of the Schick reaction as a means of determining susceptibility to the disease, and of toxin-antitoxin mixture as a means of conferring active immunity on those who are found to be susceptible. From the time of SCHICK's first publication in 1913 onwards the nature of this simple test has been frequently described in medical literature, and the character of positive and "pseudo" reactions obtained to it have been illustrated. The extensive use made of this test, and of active immunisation methods, in certain American cities, especially New York, is also common knowledge. When all due reservations are made, it seems certain that once the technique of this little test has been mastered, and experience has been gained in judging the reactions, (especially if a control test with heated toxin solution is performed at the same time on the opposite arm,) the distinction of the positive response presents little difficulty, when it can be asserted with considerable confidence that on exposure to infection diphtheria will only occur among the positive reactors.

This separation of susceptibles in itself is a valuable aid to preventive measures in times of epidemic diphtheria. It is still more valuable as an index to those members of the community at risk, who should be advised to receive active immunising treatment by toxin-antitoxin mixture, in the anticipation that they will obtain an effective immunity which is likely to last for several years. In this country, partly because other means of dealing with the spread of diphtheria are so well established, and partly through the absence of any supply of the necessary materials by public health authorities, the Schick and associated methods have been very little used in practice. Dr. COPEMAN'S presentment of the facts is derived mainly from PARK, ZINGHER, and others who have secured the adoption of these methods on a most extensive scale in the schools of New York, as well as among the general population of that city. In Great Britain the Schick test has been applied, though only on an experimental scale, at a few infectious diseases hospitals, notably those in Edinburgh and Manchester. Dr. COPEMAN'S own experience has been limited to trials of the method on a small scale, first in an institution in Bristol, and later at the Mitcham Schools of the Holborn Union. The results of these trials, which he made with the assistance of several distinguished fellow-workers, and with standardised toxin-antitoxin mixtures prepared by Dr. R. A. O'BRIEN of the Wellcome Laboratories, appears to have been generally satisfactory. In the Mitcham schools, all of 329 children, ranging in age from 3 to 14 years, were submitted to the Schick test, and 98 afforded a positive reaction. All the reactors were immunised by means of at least three separate inoculations of toxin-antitoxin at intervals of four to seven days in doses of 0·05 c.cm., 0·25 c.cm., and 1 c.cm. In three only was the reaction following the inoculation even of sufficient severity to require a day's stay in bed. Of eight adults inoculated with similar doses, none were off duty at any time, although one suffered from malaise and soreness of the arm for a couple of days. According to the view expressed in this report, the evidence of the effectiveness of the Schick method combined with active immunisation is now sufficient to make its adoption desirable in special cases. A chief instance is that of nurses and others who come into close contact with diphtheria infection. Another is the systematic use of the method in residential schools and similar limited communities. Further than this, there is the not infrequent case of parents who are specially anxious to avoid all possible risk of diphtheria infection for their children, and who are anxious and ready to accept any prophylactic method which can be recommended to them with confidence. A more difficult question is raised when it is asked whether the general application of this measure of prevention, as adopted in New York, should be recommended for English communities. The obstacles which would have to be met, before wholesale testing and inoculation could be undertaken at our elementary schools, and among the population generally, are obvious and somewhat formidable. In a note, addressed to Sir GEORGE NEWMAN and forming a preface to Dr. COPEMAN'S report, Dr. G. S. BUCHANAN expresses the opinion that it would be premature to advise such a system of general immunisation in this country. Before this could be done, it would be necessary not only to have further and longer experience of the New York results, but also to consider whether equally good results cannot be achieved by the customary measures of diphtheria prevention which we adopt, and more particularly by improved methods based on the same principles. It is clear that in some respects our traditional means of dealing with diphtheria prevalence need to be revised.

The principal directions in which revision is necessary will be found in Dr. BUCHANAN'S observations, given elsewhere in our present issue, which raise practical considerations of considerable importance. Measures of prevention in regard to diphtheria carriers ought, in view of present knowledge, to be restricted, if it can be shown to be possible, to those carriers whose diphtheria bacilli are demonstrated to be virulent. The practicability of applying this principle depends largely on the development of laboratory methods recently proposed, by which the virulence of a number of separate cultures can be tested simultaneously on the same experimental animal. The restriction of preventive measures to virulent cases would, of course, permit a very desirable economy in time and in money when dealing with diphtheria outbreaks. Another important economical consideration is raised in the portion of the report which insists that there is no good legal or practical ground for notifying the "bacteriological" carrier, otherwise healthy, as a case of diphtheria, or for removing such a carrier to an isolation hospital—often to the exclusion of cases requiring treatment. The warning given against waiting for bacteriological confirmation before giving antitoxin in cases already clinically recognised as diphtheria deserves special attention, as also do the limitations of routine swabbing at schools and hospitals. It is evident that methods of prevention based on the detection of infective cases and carriers should not be discarded in favour of the new systems of prophylaxis until further efforts have been made to improve on them in the light of newer knowledge of the carrier condition and of virulence tests. This can only be done by careful collection and study of the experience, past and future, of public may again be through ketonic acids like pyruvic, which can be converted into alanine with ammonia. The difficulty of ascertaining the intermediate stages and the methods of determining them are pointed out.

The section on catabolism contains a description of the process of digestion in animals—absorption, nutrition, respiration, excretion, and the chemical regulation by the secretions of the ductless glands. Each chapter is short, yet the essentials are well and carefully explained. The author's aim was to write a readable account of the chemical processes in living organisms. He has succeeded in doing so. The book can be thoroughly recommended to readers wanting an introduction to biochemistry, while the numerous references to larger books and to original papers will be valued by those who have been stimulated to desire more information.

Practical Biological Chemistry. By G. BERTRAND and P. THOMAS. Translated from the third edition by H. A. COLWELL. London: G. Bell and Sons. Pp. 348. 10*s.* 6*d.*

MM. G. Bertrand and P. Thomas's "Guide pour les Manipulations de Chimie Biologique" is a work well known and much appreciated in France, and Mr. Colwell has performed a good service to our technical literature by undertaking the somewhat laborious task of translation. The work is broad and practical in character and will be read with interest by students of biochemistry. It is not intended as a laboratory handbook for the specialist in pathological biochemistry or any other particular branch of the subject, but is designed to afford a suitable scheme of work covering a wide field, so as to ensure a broad foundation for any investigations the student may afterwards concentrate upon. The first portion of the work is concerned with the detection and estimation of the elements, such as copper in snails' blood, boron in wine, &c. The sugars, polysaccharides, glucosides, fatty and aromatic acids, fats, alkaloids, proteins and their hydrolysis, pigments, and so forth, follow, with appropriate methods of isolation, detection, and estimation. The second portion is concerned with enzyme chemistry and is evidently the work of Prof. Bertrand, who is a master of this subject. Hydrolases, oxidases, clastases, elements of microbiology, fermentations and the identification and estimation of the chief products of fermentation, and various synthetic phenomena are dealt with in a clear and concise fashion. A few errors occur—for instance, a wrong value is given to the specific rotatory power of maltose, and the value of the book would be much enhanced if references were given in the text.

EARLY SCIENCE IN OXFORD.

Part I., Chemistry. By R. T. GUNTHER. Oxford University Press: Humphrey Milford. 1921. Pp. 91. 10*s.* 6*d.*

PREVIOUS to the publication of the book now before us Mr. Gunther had already conferred an obligation on students of the history of science in Oxford by the issue of his Daubeny Laboratory Register, which, among other information, gave a list of scientific treatises by members of Magdalen College up to and after the erection of the Daubeny Laboratory. The earliest treatise mentioned is one by Edward Wotton, 1552, being a zoological work entitled "De Differentiis Animalium," a part of which—namely, that dealing with insects—was published by Dr. Thomas Moufet, under the title of "The Theatre of Insects, in 1634," and again edited and published together with Topsel's "History of Four-footed Beasts," by J. R., M.D., in 1658.

The present volume is the first of a series intended to deal with the history of science in Oxford in general. Part II. is to treat of mathematics, and Part III. with astronomy, and further parts are to follow supposing that financial difficulties in regard to the cost of production are overcome. If the following portions of the work are as good as that now before us Mr. Gunther may be warmly congratulated, for he has given us a most interesting account of chemistry at Oxford from the time of Roger Bacon down to the nineteenth century.

The first persons, it may be assumed, to sell what may be broadly called "chemicals" in this country were the apothecaries, and although Freind says that Johannes Falcandus of Lucca, 1357, was the first apothecary in England, Mr. Gunther points out that Wood mentions one John the Spicer who held a seld—i.e., shop—in *ypotecaria*, in the parish of All Saints in Oxford in 1332. (We can add an even earlier mention of apothecaries than this, for the Ward Robe Rolls mention one Odin the Spicer who was Apothecarius Reginæ in 1313.) After Bacon experimental science languished until the early years of the seventeenth century, but circa 1640 Oxford became the centre of scientific study in England. The protagonist was the Hon. Robert Boyle, who was the first to prepare hydrogen, and who also was the first to introduce into Oxford a regular teacher of practical chemistry—namely, Peter Sthael, "a great hater of women and a very useful man." In this century, too—i.e., in 1671—John Dwight of Christ Church took out a patent for the process of salt-glazing stoneware, and about the same time Sir Kenelm Digby and John Mayow were experimenting on the use of "the Sal-Nitro" in agriculture. Mayow was Fellow of All Souls, a great chemist, and was the practical discoverer of oxygen as put forward in his Tractatus de Respiratione. Besides the Oxford laboratories there were many in London and the suburbs, one of which was kept by Nicolas Le Fevre or Lefebure circa 1664, when Professor of Chemistry to Charles II. He wrote a work called "A Compleat Body of Chemistry," in which, amongst other receipts, he gave directions for preparing "mummy" quite equal to that prepared from "bodies dried up in the hot sands of Lybia."

To return to Oxford, the first university laboratory was founded by Elias Ashmole in 1683, and, like most other seventeenth century laboratories, was placed in a cellar to minimise danger from fire; it may be said of early chemists that, like the early Christians, they wandered in dens and caves of the earth. The eighteenth century study of chemistry in Oxford is marked by the foundation of the Worcester Porcelaine Company by Dr. John Wall, of Worcester and Merton Colleges, and by the lectures of Dr. Martin Wall, who remarked in his first lecture that "Chemistry has improved Science . . . . given occasion to the invention of gunpowder, and a coup de grâce to the miseries of war," a statement which reads oddly in the light of recent events. We need only add that Mr. Gunther's book ends with a full account of Dr. Daubeny, his laboratory, and the apparatus contained therein, a worthy finish to an excellent compilation.

GENERAL MEDICINE.

Vol. I. of the Practical Medicine Series. Edited by FRANK BILLINGS, M.S., M.D., Head of the Medical Department and Dean of the Faculty of Rush Medical College, Chicago; and BURRELL O. RAULSTON, A.B., M.D., Assistant Attending Physician and Resident Pathologist, Presbyterian Hospital, Chicago. Chicago: The Year Book Publishers. 1921. Pp. 630. $2.50.

THIS volume is the first of a series of eight, to be issued at monthly intervals, and covering the entire field of Medicine and Surgery. It is intended to summarise the work of the previous year in a handy form for the general practitioner, and is therefore somewhat similar in aim to the *Medical Annual*. This volume deals with the infectious diseases, respiratory diseases, diseases of the heart and blood vessels, endocrinology, metabolic disorders, diseases of the urinary and gastro-intestinal tracts, affections of the liver and pancreas, and deficiency diseases. It consists of a series of abstracts from papers published in the American, British, and Continental medical journals, about 70 per cent. of these being culled from the American press. There are 38 plates, gratitude. It is a serious reproach to our national medicine that we are unable to provide adequate instruction in midwifery for our students; we should not in such a connexion be using the word adequate at all, for we ought to be able to show that the best facilities for teaching so important a subject are forthcoming.

Sir WILLIAM SMYLY divided his verdict upon the examinations in midwifery into four headings and reported as follows: The examinations of the Universities of Bristol, Birmingham, Durham, Manchester, St. Andrews, Glasgow, Belfast, and Dublin, of the Apothecaries' Hall of Dublin, and of the Irish Conjoint Board were "sufficient." These ten were personally inspected. He was unable to be present at the clinical examinations in Leeds and Edinburgh, but accepted the evidence of the examiners as to the methods followed and declared the examinations "sufficient." But of the examinations of the Apothecaries' Society, the London Conjoint Board, the Universities of Liverpool, Oxford, and Sheffield, the Scottish Conjoint Board, the University of Aberdeen, and the National University of Ireland, he said "in the absence of a clinical examination I cannot consider this examination sufficient"; while of the examination of London University he said "this examination is not sufficient." The examination at Cambridge was not reported on. The exact meaning which Sir WILLIAM SMYLY attached to the word "sufficient" seems to have been uncertain, but the Examination Committee of the General Medical Council have taken a lenient view in holding that their inspector meant to warn rather than to condemn those bodies whose tests he did not find "sufficient"; it is serious enough that practically half of all the bodies inspected should require warning on so vital a matter in the training of the practitioner. It might be expected that Sir WILLIAM SMYLY, one of our wisest and most experienced obstetricians, would hold strong views on the necessity of raising the level of examinations in midwifery and gynæcology, especially on the practical side, and the Examination Committee took him to imply that, apart from the question of the clinical tests, he was not dissatisfied with the level of efficiency actually required by any of the licensing bodies, save perhaps the University of London; and he was understood not to suggest that any of the candidates who had passed the examinations of the bodies in question should have been rejected.

With regard to the University of London, that body has already taken steps to remedy conditions which were capable of being immediately improved. Additional examiners have been appointed and the well-known rule that no student should be examined by one examiner only will be more carefully insisted upon. Further, every candidate will be for the future required to furnish certificates of instruction in clinical midwifery and gynæcology. The University will have to submit to reinspection at an early date, and no doubt the authorities find the position a vexatious one, but those who know where the real fault lies will find it difficult to allot blame. The teaching of practical midwifery is exceedingly difficult in the absence of a proper number of beds for lying-in women, and there is acute need for a larger number of beds of this sort in London. Putting the public side of the matter away from our minds, the London medical student suffers by comparison both with Ireland and with Scotland in receiving very little clinical instruction in this subject, though in all others he is particularly fortunate. That domestic midwifery has enormous value no one doubts, but it ought to be accompanied and illuminated by careful demonstration in specially equipped institutions. At a recent discussion of the Obstetrical Section of the Royal Society of Medicine concerning the teaching of obstetrics to medical students, the fact emerged that the number of beds available for lying-in cases in London hospitals attached to medical schools was only 97 of a total of 5250 in the 12 hospitals, and of these 69 only were available for teaching of medical students. Since that time some improvement has taken place, and a sensible number of lying-in beds have been added to the humiliating total, but many more are required. And until they are forthcoming the teaching bodies concerned may be submitted to reproach which they cannot avoid.

The Production of Chemical Drugs.

MUCH of the recent legislation in this as in other countries bears the stamp of the war; and governments have not yet broken free from a habit acquired in times when haste in the framing of measures of protection was a factor of prime importance. The hour of extremity is as productive of good resolutions as is a New Year's eve, and it is a common experience that these resolutions fade with the morning. But a short while ago we had made up our minds that the German and his goods were to be kept at arm's length for more than one generation; yet at this very time, before the wreckage of war has been cleared away, civil, if not polite, intercourse has been established, while great German cargoes are being unloaded at our ports. In some cases the goods are welcomed here because labour conditions in Germany and the disproportionate rate of exchange enable us to obtain them at lower prices than those at which they can be produced here; in other cases we are glad to have the goods because it is difficult, if not almost impossible, to procure them elsewhere. When the war began it was at once realised that we had allowed ourselves to become so completely dependent upon Germany for our supplies of certain kinds of manufactured articles that our stores, when exhausted, could only be replenished with difficulty. As a matter of fact this position offered problems which proved insoluble with anything approaching to complete satisfaction. The main thing was to produce the wherewithal to beat the enemy, and with this supreme task to accomplish there was little opportunity to become proficient in the manufacture of things not essential to the main purpose.

Among the chief articles which had to be used sparingly because their main supply was cut off were certain ranges of chemical drugs, analytical reagents, and laboratory glassware, and the resolve was made that never again would we be caught so soundly sleeping when so much required doing. Endeavours were made to produce here what we could not obtain elsewhere, and some of the wanted articles were produced in due course and on a commercial scale. Protection was promised for these infant industries, but when the time came for these promises to be fulfilled the public had already lost some of its enthusiasm, and the question of cost, which was a trivial matter when we were spending seven millions sterling a day, had again become an important factor in our calculations. Accordingly the Government passed the Safeguarding of Industries Act. If the volume of criticism of this measure has any foundation, it would have been in the interests of commerce had the Government failed to keep its pledge; but for better or for worse the Safeguarding of Industries Act is in operation, and the question that concerns the medical profession is whether the British chemical it. Three injections of 1 c.cm. given at weekly intervals, subcutaneously, are considered sufficient to produce immunity. The method was described in our columns by A. T. Glenny, K. Allen, and R. A. O'Brien (THE LANCET, 1921, i., 1236).

Sachs-Georgi Reaction for Syphilis.—The sample of Sachs-Georgi antigen submitted is considered to give, when diluted, a denser suspension than the original antigen. This suspension of a cholesterinised extract of heart tissue is put up in the usual 1 c.cm. phials ready for diluting 1 in 10 for immediate use.

Mixed Gland Preparation.—Tabloid brand preparations of endocrine glands have also been received from the same firm. These are designed for oral administration. No. 1 tabloid is obtained from endocrine glands of the male and No. 2 from the female. In the former six gland extracts are used, and in the latter seven.

BENZYL BENZOATE CAPSULES.

(PARKE, DAVIS, AND CO., 50–54, BEAK-STREET, W. 1.)

We have received samples of benzyl benzoate put up in gelatin capsules, each containing 5 minims of the ester with an equal volume of olive oil. The contents of the capsules are clear and homogeneous. Benzyl benzoate occurs naturally in Peruvian balsam and in balsam of tolu; it may be prepared chemically by the interaction of benzyl alcohol and benzoyl chloride, or of benzaldehyde and sodium benzylate. The capsules have been prepared for use as antispasmodics in the treatment of conditions in which there is supposed to be undue rigidity or spasm of unstriped muscular tissue. Good results have followed its administration in persistent hiccough (THE LANCET, 1920, ii., 512), whooping-cough (ibid., p. 615), and asthma (ibid., pp. 808 and 920); and it has also been recommended in such various affections as excessive intestinal peristalsis, cardiospasm, pylorospasm, biliary, ureteral, and renal colic, and spasmodic dysmenorrhœa. The dose is 1 to 3 capsules, three or four times daily.

"LUKMAH" TONIC TEA.

(ELLIS DAVIES AND CO., 16, MINCING-LANE, LONDON, E.C. 3.)

This tea, which is sold in a finely broken condition at 1*s.* 10*d.* the half-pound packet, is stated to be blended with "a neutralising agent of tannin." On analysis the tannin content of the tea was found to be 13·7 per cent. and the ash 5·64 per cent. Both these figures may be regarded as typical of a tea of good quality. An infusion of the tea showed no smaller amount of tannin than is customary in normal tea. We do not think that it is wise to apply the term "tonic" to tea unless there has been addition of a drug having specific medicinal properties.

CINZANO BRUT.

(CINZANO, LTD., 43, DOVER-STREET, LONDON, W. 1.)

This is a natural sparkling wine, the product of Italy, of agreeable flavour and of a champagne character. The relatively high alcohol content and low sugar show it to be fully fermented. The composition on analysis was:—

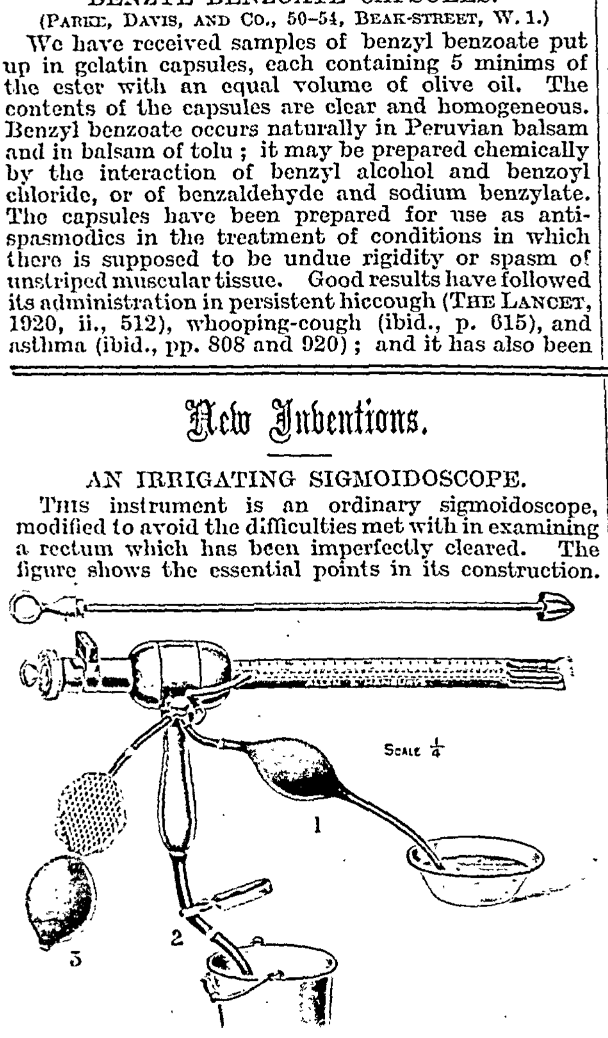
	Per cent.
Alcohol	13·55 (by volume).
Equivalent to	23·8 proof spirit.
Total extractives	2·60
Containing mineral matters ..	0·14
" sugar (as invert sugar)	1·35
" cane sugar	nil.
Total acidity as tartaric acid ..	0·7
Volatile acid as acetic acid	0·03

Preservatives, including sulphites and salicylic acid, were tested for and found to be absent.

New Inventions.

AN IRRIGATING SIGMOIDOSCOPE.

THIS instrument is an ordinary sigmoidoscope, modified to avoid the difficulties met with in examining a rectum which has been imperfectly cleared. The figure shows the essential points in its construction.



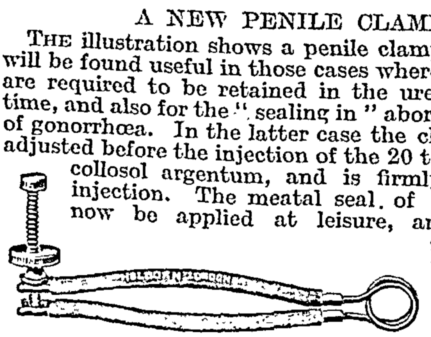
A short way beyond the eye-piece the calibre of the tube is increased to form a definite chamber, in which any remains of an enema or fluid fæces will collect without running down on to the eye-piece. From this chamber fluid can escape through the handle, which is hollow and is attached to a wide rubber tube closed when not in use by a clip (2). At the side of the chamber there is a three-way tap connected with the ordinary bellows (3) and a Higginson's syringe (1). By means of the tap either the bellows or the Higginson's syringe can be put into communication with a narrow tube which passes along the inner wall of the instrument, terminating just inside its open end. By this means it is possible to inflate the bowel in the usual way or to project a stream of water over the bowel wall. When the operator finds that there is an escape of fluid from the bowel he removes the clip from the tube attached to the handle, turns the tap so as to connect the Higginson's syringe with the narrow inner tube, and washes the bowel clean. When this is accomplished the tap is turned in the opposite direction, inflation resumed, and the examination completed. The only other point to be noted is the shape of the obturator, which is grooved at the sides to allow for the inner tube. I have used the instrument a large number of times, and although it may appear rather complicated it is quite simple to use.

Messrs. Allen and Hanburys, of Wigmore-street, London, W., have carried out my design.

ARTHUR EDMUNDS, C.B., M.S. Lond.,
Queen Anne-street, W. F.R.C.S. Eng.

A NEW PENILE CLAMP.

THE illustration shows a penile clamp that I think will be found useful in those cases where medicaments are required to be retained in the urethra for some time, and also for the "sealing in" abortive treatment of gonorrhœa. In the latter case the clamp is loosely adjusted before the injection of the 20 to 30 minims of collosol argentum, and is firmly closed after injection. The meatal seal of collodium can now be applied at leisure, and the clamp should not be removed until after the seal has hardened. The clamp will be found to be satisfactory for use with any adolescent or adult male patient. Owing to such great variations in size of the penis with different individuals the usual spring clamp is often useless. The "sealing in" abortive treatment of gonorrhœa is very valuable in suitable early cases, and any method tending to the simplification of the technique is of interest.



The instrument has been made from my design by the Holborn Surgical Instrument Company.

Harley-street, W. H. WANSEY BAYLY.

important additional resolution was directed to investigation as to the inclusion of "all dangerous drugs of whatever origin, which produce similar effects" to those named in the Convention of 1912, and to the desirability of convoking another International Conference to draw up a yet wider Convention.

The Governments of Germany and of the Serb-Croat-Slovene State have also been invited to nominate representatives on the Advisory Committee. Inasmuch as, by the terms of the Convention, medicinal opium and all preparations, both non-officinal and officinal, containing more than 0·2 per cent. of morphine are to be confined to medical and legitimate purposes, we do not see how this can be effected unless in all producing countries, whether Turkey, India, Persia, or China, the area under poppy cultivation and the actual amount of production of raw opium are brought under strict supervision and control.

SCHOOLS OF PUBLIC HEALTH IN THE UNITED STATES.

IN recent years there have been important extensions in the teaching of hygiene and public health in American universities. For many years the School of Technology at Cambridge, Boston, which is closely affiliated with Harvard University, has led the way in the training of men for public health work. The late Prof. W. T. Sedgwick was the leader in this movement, and many of the most distinguished public health workers in the States owe their inspiration to his teaching and example. With his work Prof. G. C. Whipple was closely associated, and Dr. C.-E. E. A. Winslow, professor of hygiene in Yale University, is one of the most distinguished alumni of this school. These three and many others trained in the same school were non-medical graduates; and although a few of the non-medical graduates from the school have become the heads of State Boards of Health, most of them have become sanitary engineers and advisers on water and sewage and allied problems, and have not been engaged in public health administration as it is understood in England. The question as to whether there is a large need of public health experts of the highest grade who do not start as medical graduates is not under discussion at the moment; but it is noteworthy that in the States, as the country has become more fully settled, official public health posts are being generally occupied by medical men, though many of them, unfortunately, are destitute of training for their special work. At Harvard and Yale Universities excellent courses of instruction in public health work are given, and, as in a number of other universities, there are elaborate courses of instruction for social workers, and for nurses and public health nurses. But until the School of Hygiene and Public Health was opened at Johns Hopkins University, under the distinguished directorship of Dr. W. H. Welch, it cannot be said that the needs of those medical men wishing to be trained for a public health career were adequately met. The courses at this new school contemplate certificates after one and degrees after two years' work, and include a very thorough practical training in the foundation subjects of public health, physiological hygiene, chemistry, dietetics, zoology and protozoology, bacteriology, &c., as well as training in epidemiology and vital statistics and in applied public health. The endowment of the school is derived from the Rockefeller Foundation, and is adequate in amount to ensure that professors and associate professors each has ample opportunity for that combination of research and teaching which keeps teaching alive and prevents it from becoming mechanical and stereotyped.

The Johns Hopkins school has been successfully launched; and now we learn that the same beneficent foundation has endowed a similar school at Harvard University with the munificent initial gift of one and three-quarter million dollars. That the new school will justify its existence, and will have an important influence on public health developments in America may be safely prophesied. Its success, like that of its predecessor at Baltimore, will become more rapid so soon as one or more States can be induced to make it a condition of holding their public health appointments that candidates shall possess a satisfactory diploma or degree in public health.

EPIDERMOID CYSTS.

Dr. Henry H. Sherk[1] of Pasadena, California, who gives a brief résumé of 15 cases, on 11 of which he operated himself, remarks that epidermoid cysts are of fairly frequent occurrence, but are almost invariably unrecognised, being generally mistaken for sebaceous cysts. They have been variously termed atheromata, inclusion cysts, implantation cysts, and epidermoids (Franke). Only the elements of the epidermis are found in the wall and contents of these cysts. Some are undoubtedly traumatic in origin, and others are with equal certainty congenital. Those of traumatic origin grow more slowly and are of smaller size than the congenital, as embryonal cells have a greater ability to grow. Writers differ as to the most common site of these tumours. In the present series the cysts were found in the following situations: scalp, 4; back, 2; shoulder, arm, cheek, lower jaw, neck, breast, groin, buttock, and finger, 1 each. In two cases there were multiple cysts, the remainder were single. Seven were in men and eight in women. The cysts always appeared as more or less hemispherical nodules, projecting from the body surface, a few unattached to, but the majority fixed to the skin and freely moveable on the subjacent tissue. The overlying skin, with few exceptions, was firmly attached to the cyst. Epidermoids are not flattened like sebaceous cysts, nor, like them, can they be moulded or changed in shape. They are also differentiated from sebaceous cysts by the absence of an opening or duct by which their contents can be expressed. The pearly lustre and laminated appearance of the contents constitute their most noticeable characteristic, the final diagnosis being made by histological examination, which shows only the elements of the epidermis.

HYDATID FREMITUS.

THE description and explanation of hydatid fremitus or thrill given in the text-books is somewhat contradictory. Some writers say that it is pathognomonic of hydatid cyst; others, that it may be elicited in other forms of cyst. Prof. L. E. Barnett has contributed to the *New Zealand Medical Journal* for October a valuable paper which does much to clear up the confusion on the subject. He finds that two forms of vibration can be elicited on percussing fluid tumours. The first is an ordinary fluid wave vibration which is not peculiar to hydatid cysts, but occurs as a rare manifestation in certain thin-walled cysts in close contact with the abdominal wall. It may be felt in a very large hydronephrosis, parovarian and mesenteric cysts, a hugely distended bladder, ascites, and a unilocular hydatid cyst. This form of fluid vibration will be familiar to clinicians. The distinctive feature of the true hydatid thrill was first clearly described by Briançon in 1828. It is the exquisite spring-like vibration which is distinctly prolonged beyond the moment of percussion, and which is associated with the remarkable drum-like resonance heard on auscultatory percussion. Hydatid fremitus of this character alone is pathognomonic of hydatid cysts. It is of extreme rarity. Prof. Barnett has been quite sure of its presence only in seven cases, although he endeavoured to elicit it in over 300 cases of hydatid cyst. In every case in which it was demonstrated the following physical conditions were present: 1. The mother cyst was close under the parietes. 2. Its walls showed signs of degeneration, leading to a slackening of the high tension that normally exists in hydatid cysts. 3. Some large daughter cysts were present, not closely health officers, medical officers of isolation hospitals and schools, with the closest possible association of the bacteriological laboratory in their investigations. It is satisfactory to note that the Ministry of Health are continuing to obtain the facts from all these sources, as well as from special research being conducted by the Medical Research Council, in the hope that before long it will be possible to obtain scientific authority for a code for the prevention of the spread of diphtheria as definite as that which we now possess in the cases of enteric fever and small-pox.

---

The Therapeutic Possibilities of B-Vitamin.

The absence of B-vitamin from food has hitherto been associated mainly with those severe symptoms collectively grouped together as beri-beri: hence this vitamin is often referred to as the anti-neuritic factor. But though these manifestations are the final result of the long-continued consumption of food entirely lacking, or containing a little but not enough of, this vitamin, the earlier signs appear to be of even greater importance. **McCarrison**, who has studied this aspect of the disease with such care in animals and man, considers that the earlier symptoms are referable to the digestive and endocrine systems, and only the later ones to the nervous system. In the early stages he has recorded loss of appetite, indigestion, flatulence, abdominal pain due to gaseous distension of the hollow viscera, headache, giddiness, weakness, coldness, breathlessness; and at a later stage chronic constipation, colitis, appendicitis, intussusception, stasis, and gastro-duodenal ulcers. Post-mortem examination showed atrophy of thymus, pancreas, spleen, and all endocrine organs except the adrenals, which were enlarged. **Cramer, Drew,** and **Mottram** record in our present issue (p. 1202) that rats fed on a diet deficient in B-vitamin showed a shrinkage of thymus and spleen, almost complete disappearance of Peyer's patches and lymphoid tissue in general, and a diminution of small lymphocytes in the blood. A state of marasmus is associated with this atrophy of lymphoid tissue and is apparently the specific effect of the absence of B-vitamin. In concluding from their observations that B-vitamin is not necessary for the life of each individual cell, and that its presence is necessary solely for the normal functioning of lymphoid tissue, the authors enter upon more debatable ground. If the effect of absence of B-vitamin were limited to the atrophy of lymphoid tissue and production of marasmus, such a conclusion might be justifiable, but their theory will scarcely account for the complexity of symptoms in beri-beri. The article by Dr. **Samson Wright**, on p. 1208, draws attention to the loss of appetite of animals fed on a diet deficient in B-vitamin, the quantity eaten being dependent on the apparent quantity of B-factor in the food.

Of the three vitamins, the B-factor seems most closely connected with metabolism, growth, and health. Several workers have observed a connexion between food assimilation and the amount of B-vitamin in the food, and it is surprising that while each of the three vitamins have long been used as specifics for certain diseases, the general therapeutic and tonic possibilities of B-vitamin have not been further explored. This subject offers an almost virgin field to the general practitioner anxious to do some useful clinical research, and we commend to his attention the therapeutic considerations advanced by Drs. **Cramer, Drew,** and **Mottram** as well as the suggestions of Dr. **Samson Wright**. Carbohydrate and fat metabolism seem dependent upon a proportionate amount of B-factor per calorie ingested. This connexion suggests the administration of B-vitamin in cases of diabetes to assist the utilisation of sugar. The addition of cod-liver oil or butter (fats rich in A-vitamin) to a diet deficient in B-vitamin has been shown to cause loss of weight and ill-health, while an increase in amount of B-vitamin led to assimilation of the fat with renewed health and growth. Cases of marasmus in infants, which had failed to put on weight by the usual treatment, began to grow directly they were given extra B-vitamin. As long ago as 1917 A. F. **Hess**[1] found that although yeast, which is rich in B-vitamin, apparently possessed little or no value as an antiscorbutic, it proved an excellent stimulant of growth in infants; he showed graphs of infants of under 1 year, 1½, and 2 years old who had maintained an almost constant weight for weeks or months in spite of various changes in diet, and showed an immediate and continuous rise after the administration of autolysed yeast. In some cases the appetite was stimulated, but in others there was a prompt response though the total food intake was not increased. That the yeast had a favourable effect on the digestive processes was shown not only by the increase in appetite, but by the improved character of the stools.

The chief source of B-vitamin in our food is the seeds of cereals and other plants, but the factor is removed from cereal seeds in the process of milling. Sugar, sago, and other farinaceous products are lacking in B-factor, meat and fish are poor, offal and eggs in comparison rich. Vegetables and milk contain small amounts. The quantity in these foodstuffs is scarcely sufficient to balance the large carbohydrate consumption of white flour in our diet, unless eggs, fruits, and vegetables are eaten in great quantities. The products richest in B-vitamin are the germ of cereals and yeast. Germ as such is not consumed by humans (except in wholemeal bread) and the yeast used in baking bread is not sufficient. Yeast contains B-vitamin in great concentration, and palatable preparations made therefrom can compensate for the lack of B-vitamin in other foods. No ill-effects have been ascribed to too great a consumption of foods rich in B-vitamin, and it is likely that certain cases of vague ill-health would be improved by the consumption of additional quantities of B-vitamin. There is here a promising field for clinical research.

The Teaching of Practical Midwifery.

At the recent meeting of the General Medical Council the Report of the Examination Committee on the latest series of inspections of the qualifying examinations furnished material for an important debate, and will have given rise to much reflection in the Council as well as outside. The inspectors for medicine and for surgery reported that the examinations held by 23 of the bodies empowered to grant legal qualifications were satisfactory, but the inspector for midwifery and gynæcology, Sir **William Smyly**, had no such tale to tell. There is no part of the practitioner's work so anxious and so responsible as his work as obstetrician, and in no department of his duties are skill and watchfulness so repaid in the saving of life, in the prevention of sickness and deformity, and—a very practical addition—in the earning of unstinted tration—the provision has been made in the Ministry neurasthenic hospitals for the accommodation and treatment by trained medical officers of the cases referred to in the question.

---

[1] American Journal of Diseases of Children, 1917, xiii., 98.

What question and answer did not elicit was whether the provision of "Ministry neurasthenic hospitals" has been sufficient, and whether the combination of the neurasthenic hospitals with hospital treatment under the control of the Minister of Pensions is achieving success. It must best be known by the relatives of patients, and by medical men whose advice has been invoked independently of the Ministry, whether the neurasthenic hospitals referred to are full and overfull, or are able to receive suitable cases whenever they arise; and, also, whether the treatment afforded in hospitals under the Minister's control is always the most suitable for the individual case. We are inclined to believe that the question of the Minister's control may sometimes prevent the patient's treatment at an institution which would be open to him, and suitable for his case, and that questions of economy may intervene to render the treatment of ex-service men mentally affected less effective than it should be. Their case and that of their relatives is a very hard one. In many instances the disability will continue for a long time or perhaps will be permanent. The removal of all certified ex-service men from public asylums would no doubt entail some expense to the Treasury, but camps and buildings must now be standing vacant and under Government control the use of which, it is submitted, might be seriously considered. Moreover, the treatment now accorded is not being given without expenditure. The public is rightly jealous of increased expenditure by any Government department, but the removal of the stigma of the asylum from sailors and soldiers broken in the war would make an appeal to universal sympathy.

MONOPOLY IN POISON GAS.

WERE it not for such lurid writing as Mr. H. W. Nevinson's account of his visit to the great American poison gas-works at Edgewood, Baltimore, in the *Manchester Guardian* for Dec. 2nd, interest in gas warfare might be said to be flagging. The fact that Major V. Lefebure's "Riddle of the Rhine"[1] deals in great part with the history of gas warfare, and the production of war chemicals does not commend the book to the medical any more than to the general reader at the present time. Nevertheless, it conveys a lesson for peace conditions, as for war, which cannot be regarded lightly by the great nations other than Germany. Major Lefebure, himself a trained chemist, had opportunities for investigating his subject from many points of view, first in the field of battle, later as a liaison officer, and finally as a member of Inter-Allied Missions to the German Chemical Factories after the Armistice. With this first-hand information he has been able to place the issue before the public with praiseworthy clearness. He shows in detail how the success with which Germany was able to deluge the Allies with new and unexpected poisons was directly due to the facilities provided by her highly organised chemical industry. The toxic materials employed in war were organic compounds prepared in great part from the same raw materials as had been used in peace-time for the manufacture of synthetic drugs and aniline dyes. In most instances, details of which are given, the manufacturing plant normally devoted to the production of ordinary commercial products was adapted with only slight modifications for the elaboration of deadly poisons. A striking example is mustard-gas, which was manufactured on the lines ordinarily followed in the preparation of synthetic indigo. Even for explosives the chemical factories provided the essential elements, notably the Haber nitrogen fixation plant, by means of which ammonia and nitrates could be obtained when supplies of nitre were stopped. The facilities enjoyed by Germany in the secret and rapid provision of these war materials were in strong contrast with the difficulties encountered by the Allies, who not only had to build new and specialised factories for the manufacture of special substances, but in many cases to institute difficult and prolonged research before methods suitable for full-scale production could be elaborated. For the future the moral is obvious. If wars are to recur any huge organic chemical industry must be regarded as potential armament in the modern sense, and it would be in the highest degree inadvisable that one country alone should possess this overwhelming initial advantage. But apart from any consideration of war, it is not to the advantage of any branch of scientific progress in other countries that Germany should in future retain the dominant position that she has had in the past in the realm of chemical research and manufacture.

EXPERIMENTAL RICKETS.

PRELIMINARY reports of the work done by Dr. E. Mellanby on the causation of rickets have appeared in previous numbers of THE LANCET.[1] The present monograph[2] gives the experimental evidence on which these reports were based, and it brings up to date the record of five years' work and the result of observations on no less than 400 puppies. A brief account is given of the earlier experiments which led to the exclusion of certain possible causative factors and which pointed to rickets being a problem in dietetics, more particularly centring round a disturbance in calcium metabolism. The criteria by which the presence or absence and the severity are to be judged are discussed and compared; the external appearance of the puppies, radiograms of their bones, the calcium contents of the shafts of the bones, and the histological appearance form the basis for report. There is general agreement in the results obtained by these methods, though there are occasions when some difference is apparent, differences which are in part capable of ready explanation and which in part point out the need for further research. The earlier experiments led to the evolution of a diet which produced rapid and marked rickets in well-growing puppies. This diet remains the basis of the later work except that the amount of bread it contains was controlled in the later experiments. By additions to this basic diet of fats and oils the relative anti-rachitic influence of the various substances was estimated: thus it was found that cod-liver oil had the most effect in promoting calcification of bone, and linseed oil and babassu oil little or no effect. The question is discussed as to whether the anti-rachitic factor, which ricket-preventing substances are presumed to contain, is the same as fat-soluble A-vitamin, and from the identity in distribution in the several fats and oils and their mode of action the author inclines to the view that anti-rachitic and fat-soluble A-vitamins are the same. There are interesting experiments testing the activity of other food factors in the ætiology of rickets. Thus it was found that protein has a definite anti-rachitic effect while carbohydrate tends to promote the development of rickets. Further experiments bear on the question of exercise in its relation to rickets, and the author compares its influence to that of protein in preventing or modifying the disease.

The author takes a wide view of the subject, as is evident from the short summary given above, besides which other factors, such as infection and the possibility of thyroid extract modifying the disease, are discussed. In fact, while there were at one time two somewhat opposed schools of thought, the one holding the view that rickets is a food-deficiency disease and the other maintaining that it is primarily the result of bad external environment and deficient exercise, Dr.

industry, not to mention other trades whose products so intimately concern the medical profession, will be able, as a result of the protection afforded, to produce here articles which at present are mainly imported. We hope sincerely they will, but it must be admitted that the circumstances at the moment do not favour them. The Act is to remain in force for five years only, and as Germany has had forty years' start, the period of protection is brief. Again, between the introduction of the Bill and the enforcement of the Act several months elapsed during which importers had the opportunity, which they did not fail to employ, to bring into this country, free of duty, large supplies of those articles which are now subject to a tax of 33⅓ per cent. So considerable were the imports of some of the products that there is said to be a sufficient stock of them to satisfy the country's requirements for a very long time, and thus, in effect, a part of the five years' period of protection is lopped off and the industries concerned are discouraged from the start. The next question is whether the duty will be sufficiently high to serve its purpose, and to this no general answer can be given at any rate in respect of chemicals. The protected list of chemicals contains something like five thousand articles, and possibly more than a third of these are not at present made in this country; a large proportion of the latter are rarely used either in medicine or the arts or commerce, and it is estimated that so far as this proportion is concerned it is extremely unlikely that it would be worth the while of any manufacturer to undertake their production here. Further, it is alleged to be physically impossible to produce here several of the protected articles, so that by taxing the importation of such articles as santonin and menthol no British industry can ever be safeguarded. Incidentally, however, a referee is now hearing a complaint against the inclusion of santonin in the list, and as it is understood that the duty on menthol is to be modified, for the moment comment on the inclusion of these two articles must be in abeyance.

The Act provides that "synthetic organic chemicals, . . . analytical reagents, all other fine chemicals (except sulphate of quinine of vegetable origin), and chemicals manufactured by fermentation processes" are to be subject to an import duty of 33⅓ per cent. The Board set up under the Act has not the power to exclude from the list any article which falls in these categories. In compiling the list the Board has given to the term "fine chemicals," a wide interpretation that is now being challenged. Should it be established that the Board's view is correct, the only remedy open to the complainants will be an amendment to the Act, and we believe that already an amending Act is suggested which, without taking away any safeguard from British manufacturers, will secure an unhampered supply of desired products which are not likely to be produced here economically within the space of five years. So far the operation of the Act has not affected values in a general or substantial way. This is due to three causes: the large quantities of articles brought in before the duty was imposed, the bad state of trade resulting in keen competition among dealers for orders, and the low exchange value of the mark. As time goes on stocks on which no duty was paid will become depleted, and prices may then advance to the full extent of the amount of the duty, unless the Act has the desired effect and enables our manufacturers to compete with foreign producers; for trade must in time improve, and holders of stocks will become firmer in their views, and finally the exchange value of the mark will not be such an important factor, since the German manufacturers are now compelled officially to quote in sterling. Taking a broad view of the situation, while the principle of the Act, namely, the protection of essential industries, may be sound, we think it would have been in the interests of all concerned—the producer, the dealer, the prescriber, the chemist, and the ultimate consumer—had Parliament set up, under the Act, advisory committees representative of all interests, for the purpose of laying down the articles which should be protected. In the event of an amending Bill being framed we suggest that this principle should be adopted.

Annotations.

"Ne quid nimis."

OPIUM AND THE LEAGUE OF NATIONS.

PROGRESS has been made with the putting into force of the Opium Convention by the League of Nations since we last referred to the subject.[1] Both the Assembly and the Council of the League have had before them the report of the Advisory Committee appointed by the Council on the recommendation of the first Assembly, which met in December, 1920. This report of the Advisory Committee which held its first meeting in May of 1921, and which will meet again in the early part of next year, was considered and reported upon by Commissions both of the Assembly in September last and by the Council in October. It appears that the Council of the League on June 28th last approved of request being made to all Governments, whether members of the League of Nations or not, to ratify the Convention as soon as possible. They further resolved that Governments party to the Convention should prevent the export of the drugs named in the Convention (opium, morphine, heroin, cocaine, &c.) to other countries unless the Government of such importing countries approved thereof and certified that the drugs would be used for legitimate purposes. They also resolved to direct the attention of contracting Powers having treaties with China to the need for prevention of contraband trade in opium and other dangerous drugs. Moreover, as we intimated in September, the Council in June last took a step in advance of the Advisory Committee's report and resolved:—

> That in view of the world-wide interest in the attitude of the League towards the opium question, and of the general desire to reduce and restrict the cultivation and production of opium to strictly medicinal and scientific purposes, the Advisory Committee on Traffic in Opium be requested to consider and report, at its next meeting, on the possibility of instituting an inquiry to determine approximately the average requirements of raw and prepared opium, specified in Chapters I. and II. of the Convention, for medicinal and scientific purposes in different countries.

The second Assembly of the League of Nations, recently held in Geneva, on the report of its Commission No. V., adopted, in the main, the resolutions of the Council of June, though with a few rather important amendments as well as with some additions. Lastly, the Council, on Oct. 17th, adopted a report containing the Assembly's resolutions as amended and added to. Perhaps the most important amendment made was that of the Council's own resolution of June 28th, quoted verbatim above, in reference to restriction of the production of opium. The limitation to "strictly medicinal and scientific purposes" was struck out and "legitimate purposes" substituted therefor. This modification of the Council's previous resolution was, as explained to the Assembly, "to meet the very special conditions obtaining in various countries, particularly in India, where opium is largely employed as a prophylactic or an effective remedy" without medical advice or prescription. The most public supply by the addition of chlorinated lime. The 65-year old man on whom the inquest was held, on returning home after a day of strenuous activity, retired to bed feeling ill; vomiting and purging set in, and he died stuporous about 30 hours after. His house was situated about half a mile from the well where chlorinated lime was added to the water, and no discomfort or illness accredited to the water-supply was reported from any of the intermediate 25 or 30 connexions along the main. Assuming that the deceased man drank as much as two quarts of public water daily, he would have taken no more than one-eightieth of the curative dose of chlorinated lime as set down in the American Pharmacopœia. Fortunately for the credit of the water, an expert pathologist of the University of Pennsylvania performed an autopsy which showed no evidence of inflammation of the alimentary tract and led him to the opinion that death was due to dilatation of the heart, possibly brought on by exertion in a subject of marked arterio-sclerosis. This autopsy took place six days *after* the jury's verdict and led to a re-empanelment, when a supplementary report was issued "that chlorine was neither directly nor indirectly the cause of death." The fact that the present constitution of society makes it difficult to overtake a lie was, we presume, the reason for reporting the case fully in the last issue to hand of the U.S. Public Health Reports.

FURTHER WORK ON EXPERIMENTAL TAR CANCER.

WE have referred recently to the importance of this new line of experimental cancer research. How actively work in this direction is proceeding is evident from the fact that we have to record the publication of two further papers on this subject from two new centres of cancer research. One by Dr. Deelman[1] is dated from the Antoni van Leeuwenhoek House in Amsterdam. Both carcinoma and sarcoma were produced as the result of the repeated application of tar to the skin of mice. The paper is in the Dutch language, so that, unfortunately, its contents are not readily accessible. But the author expresses the opinion that he has observed in one case a carcinoma arising from a benign growth. The other paper[2] by Prof. B. Bloch, the Director of the Dermatological Clinic in Zurich, and his assistant, Dr. W. Dreifuss, registers a further advance, because these authors have succeeded in locating the cancer-producing agent of coal tar in the fraction with a boiling-point of over 300. This fraction is soluble in benzol and retains its activity after distillation. This fraction gave the remarkable result that 100 per cent. of the mice to which it was applied gave rapidly growing carcinomata within four months. The malignant character of these tumours was established by their morphology, by their infiltrative and destructive growth, and by the spontaneous formation of metastases in lymph glands and lungs. The hydrocarbons with a lower boiling-point also produced tumours, but these were of a benign character. It is probable that further work along these lines will yield important and novel information on the difficult and much debated problem of the relationship between benign and malignant new growths. A further communication dealing in detail with the chemical aspect of the various tar fractions and their biological properties is promised. Another interesting observation by these authors is, that while tumours could be produced in rabbits and in mice by the application of tar, guinea-pigs have so far failed to react in the same manner. Although the authors do not comment upon this negative result, it is of interest, because it emphasises the susceptibility of the cell as an important factor in the genesis of cancer. Differences in the susceptibility of cells to react to a given irritant by the cancerous change exist not only between different species, but between different individuals in the same species, between different tissues in the same individual, and even between different cells in the same tissue.

METEOROLOGY AND BACTERIAL INFECTION.

THE season is one when the "common cold" is in evidence and when the doctor's inability to prevent or cut it short is apt to lead to some reproach of medical skill. Something might be hoped from a collective study of the medical reports available under the Insurance Acts. Do the colds of sedentary workers last longer than those of outdoor workers? Does keeping the house answer better than going out? Are summer colds the most intractable? The answer to questions such as these is outside any possible individual experience but should be within the scope of concerted inquiry. In the meantime help is welcome from any source, and certain passages in Dr. E. J. Butler's recent address to the Association of Economic Biologists are, at all events, suggestive. In the absence of a blood-supply and of anything resembling a mucous membrane, the plant can hardly be expected to throw any direct light on catarrhal conditions in animals. But Dr. Butler, who is director of the Imperial Bureau of Mycology, has found one direction in which plant disease may have a bearing on the problem. He has shown that such relatively small variations of temperature as 8 or 10° C., and of humidity as 5 per cent., are sufficient in certain cases to determine whether a parasite can cause a 100 per cent. infection or none at all. Plants lend themselves to such study inasmuch as they can be grown under constant conditions of humidity and temperature in special chambers when the exact relations of their diseases to the environment can be determined. This relation, singularly close in some cases, has to be worked out on the parasite and host together, for the host-parasite complex, as it is called, does not always behave in the same way as either alone. Parasites that are perfectly harmless under one set of conditions will infect freely under conditions not very widely different. We should like to see the main facts of this relationship in plant diseases brought up for discussion at one of the societies specially interested in climatic medicine. The way has already been prepared by such a study as that of Colonel C. A. Gill on the Rôle of Meteorology in Malaria in a recent issue of the *Indian Journal of Medical Research.*

SELF-DISINFECTION IN THE CAMPAIGN AGAINST VENEREAL DISEASES.

IN the *International Journal of Public Health* for November–December, 1921, this question is discussed by Sir G. Archdall Reid, who advocates the instruction of the individual in methods of self-disinfection, and by Dr. Otto May, who presents the case against. Both articles should be read, but much that they contain is mere beating of the wind. It is a matter of regret that the protagonists on both sides of this question cannot see their way to join hands and oppose a united front to a common evil, for there is a line of research, not likely to be barren, to which they might well devote their attention.

The present state of affairs is confusing and annoying. Both parties to this discussion, and the societies which they represent, are agreed that "the best way of avoiding venereal disease is to abstain from promiscuous sexual intercourse." That is the ideal, but human nature and civilisation being what they are, Sir Archdall Reid holds, in effect, that the ideal is unattainable. He is persuaded of the futility of "exhortation" and advocates that "prospective sinners shall receive instruction in disinfection." How this instruction is to be imparted he does not sufficiently make clear. If it is to be given by posters displayed in lavatories, worded so ambiguously that they will not convey their full meaning to "an innocent boy," it seems to us it will do more than fail. Yet this is one means by which Sir Archdall Reid suggests the necessary information should be disseminated. In packed but having room to vibrate in contact with the walls of the parent cyst. The signs given when other physical conditions are present may be summarised as follows: single tense cyst—no thrill; single slack cyst—a wavy fluctuation but no thrill; cyst with daughter cysts tightly packed—no thrill. Prof. Barnett tried to verify these observations experimentally, using an imitation mother cyst made from the inner tube of a motor tyre and daughter cyst made from finger-stalls distended with water, but, like previous experimenters, not with unqualified success. It is here exceedingly difficult to reproduce artificially the exact conditions met with in nature.

THE HERITAGE SCHOOL AT CHAILEY.

THE present financial position of the Heritage Schools of Arts and Crafts for Crippled Boys and Girls at Chailey, in Sussex, is a cause of anxiety to those who are responsible for the work there carried on. An appeal for funds is issued by Princess Louise, Duchess of Argyll, Chief Patroness of the Schools, supported by the Bishop of London (President) and Sir Robert Jones (Chairman of the Surgical Board); the increased cost of upkeep of all kinds—repairs to buildings, wages of staff, food, &c.—has rendered necessary an augmented income for this most well-deserving institution. Founded in 1903, the schools have harboured 860 children up to the present time; of these the boys have been trained in woodwork of all kinds, particularly toy and cabinet making, and the girls in needlework and children's dressmaking. At the completion of their courses, equipped with a means of earning their own livelihood, they are placed with well-known firms. During the war 590 shell-shocked children were cared for, and a hospital was opened which housed in all some 600 wounded soldiers. The recent gift, by Sir Jesse and Lady Boot, of an operating theatre has greatly increased the means of dealing with paralysis, rickets, and congenital deformities. Sir Robert Jones speaks of the institution as having enormous possibilities of development, given sufficient financial support—making mention of electric light and an improved water-supply as immediately desirable. It is to be hoped that, even in these days of reduced subscriptions, the season of the year will not be without its effect upon the balance-sheet at Chailey.

THE INFLUENZA BACILLUS IN CULTURE.

THE recent epidemic of influenza stimulated a number of researches into the biological properties of *B. influenzæ*. Important new facts have been added, chief amongst which may be mentioned the demonstration of a soluble toxin, serologically differing races, and the production of indole. In addition, much light has been thrown on the substances required for the growth of the bacillus. This of necessity opened up the old controversy as to whether the bacillus was capable of growing in pure or impure cultures in the absence of blood. At the present moment the majority of workers seem agreed that *B. influenzæ* in pure culture cannot be grown in the absence of blood or some derivative of it. With regard to the behaviour of impure cultures there is some difference of opinion. Catani,[1] and more recently Thjotta,[4] as well as Williams and Povitzky,[6] claim to have obtained growths of *B. influenzæ* in mixed cultures in the absence of blood pigment. On the other hand, contemporary workers refuted Catani's claims (Ghon and Preyss [2] and Luerssen[3]), whilst among modern workers Fildes,[5] Rivers,[7] Putnam and Gay,[8] Davis,[9] and others have obtained uniformly negative results. Catani apparently failed because the test employed by him for the absence of hæmoglobin in his media was not sufficiently delicate; he made use only of the spectroscope as a test for blood pigment. It is now known that minute quantities of blood too small to be detected by this means are quite sufficient for the growth of the bacillus of influenza. The findings of some of the more modern workers are open to the same criticism.

As already indicated, the actual nature of the substance or substances required for the growth of *B. influenzæ* has also been the subject of considerable inquiry. It has been determined that two factors are necessary, both of which are to be found in blood—one derived from blood pigment and the other from the non-pigment fraction (Fildes). We have used above the term blood-pigment factor instead of hæmoglobin, for the fact is that hæmoglobin itself is incapable of allowing growth, which is determined rather by traces of methæmoglobin present. Ordinary human blood-agar grows *B. influenzæ* only feebly, while if the same medium has been just brought to the boil luxuriant growths are obtained (Levental's medium). The chief effect of the heating apparently is to change the hæmoglobin into methæmoglobin or some pigment derivative. This pigment-derived substance is heat-resisting, and with one exception (Thjotta) has not been found outside blood. Thjotta's results are so diametrically opposed to those of Fildes, Davis, and others that they cannot be accepted without further proof. The second substance necessary for the growth is heat-labile; as well as in blood it has been found in various animal and plant tissues (yeast and potato extracts). Although in agreement with Terada's claim [10] that the bacillus of influenza should not be called *hæmoglobinophilic*, the researches enumerated above do emphasise its strictly *hæmophilic* nature.

EX-SERVICE MEN MENTALLY AFFECTED.

Two questions asked in the House of Commons shortly before it adjourned related to the care of sailors and soldiers who took part in the war and whose minds, as the result of their service, have become affected. The whole subject of the conditions in which such men are treated is unquestionably one in which not only their relatives but the public are deeply interested. It is felt by many that a clear distinction should be made between those who, through fighting in the defence of their country have become of unsound mind, and those other unfortunates who are the normal inmates of "lunatic asylums"—we use the historic term intentionally. The first of the questions referred to, asked by Capt. C. E. Loseby, M.P., elicited the reply that there are now about 6210 ex-service men receiving treatment in county or borough asylums at the cost of the Ministry of Pensions, and that of these 4110 have dependents eligible for and in receipt of treatment allowances—that is to say, that they receive payments dependent upon the degree of mental incapacity affecting the man in the asylum. The slur attaching to the wife, and even more to the children, of the man known by their neighbours to be in an asylum falls upon them. The second question, asked by Mr. Gillies, M.P., had reference to the provision of institutions by the Board of Control for ex-service men, who are not certifiable as of unsound mind. From the reply it is gathered that there are no such institutions in existence, and secondly, that as to this class of case, steps have been taken by the Ministry of Pensions to secure for all uncertifiable ex-service officers and men, whose condition is due to war service, hospital treatment under the control of the Ministry, entirely independent of lunacy adminisauthorised to call a special meeting of the Education Committee for this purpose should it be found necessary before the beginning of the May session.

On question put from the chair, the chairman of the Education Committee was requested to hold a meeting of as many of the conveners of the committees as was possible that afternoon, with a view to accelerating the preparation of the Scottish and Irish conjoint reports and of the final report.

In a further oral interim report the chairman of the Education Committee indicated some of the steps proposed in order that the standard of preliminary examination should in accordance with the Council's resolution be raised to the level of that required in other learned professions; and that from Jan. 1st, 1923, all students should be required as a condition of registration to pass an examination in General Education equivalent to that required by British universities from matriculants in Arts or pure Science, and proposed that his interim report should be entered in the minutes; but that the discussion thereon should be postponed.

After some discussion an amendment, proposed by Sir SYDNEY RUSSELL-WELLS and seconded by Dr. RUSSELL, that the debate on the motion be adjourned, was agreed to. The Council then adjourned.

SATURDAY, NOV. 26TH.

The Report of the Examination Committee.

Dr. NORMAN WALKER, chairman of the Committee, presented this report on the series of inspections of qualifying examinations, and began by a reference to the comparatively short time occupied by the inspection. The first inspection took place in April, 1920, and all the inspections, with the exception of those of the midwifery examination at Cambridge, the surgery examination of St. Andrews, and the examinations of the National University of Ireland held in Cork and Galway, had now been completed. The inspectors on medicine and surgery had reported that all the examinations were "sufficient," but they had made numerous suggestions for the improvement of examinations, many of which they reported to be already excellent. The report of the inspector on midwifery required closer consideration. The examination in midwifery of the 23 licensing bodies were divided into four classes, as follows:—

1. The inspector reported after personal inspection that the examinations of Bristol, Birmingham, Durham, Manchester, St. Andrews, Glasgow, Belfast, and Dublin Universities, the Apothecaries' Hall of Dublin, and the Irish Conjoint Board were "sufficient."
2. He was unable to be present at the clinical examinations in Leeds and Edinburgh, but accepted the explanation of the examiners as to the methods they followed and declared the examinations "sufficient."
3. Of the examinations of the Apothecaries' Society, the London Conjoint, the Universities of Liverpool, Oxford, and Sheffield, the Scottish Conjoint Board, the University of Aberdeen, and the National University of Ireland, he said, not always in the same words, but always apparently with the same meaning, "in the absence of a clinical examination I cannot consider this examination sufficient."
4. Of the examination of the University of London he said "this examination is not sufficient."

It was manifest that Sir William Smyly held strong views on the necessity of raising the level of the practice on midwifery and gynæcology, and of examinations in these subjects; his varying forms of expression suggested warning rather than condemnation of the bodies included in Class 3.

The Committee did not understand Sir William Smyly to mean that, apart from the question of a clinical examination, he was dissatisfied with the standard of proficiency actually required by any of these licensing bodies, or that any candidates passed the examination who should have been rejected. The Committee was in full sympathy with the inspector's object of raising the standard of examination and practice; and while it recognised the difficulties associated with a clinical examination in midwifery and gynæcology, it regarded the matter as of such importance that it recommended the Council to draw the attention of the licensing bodies in Classes 3 and 4 to the inspector's report. With reference to Class 4, the body concerned, the University of London, had adopted resolutions, now in operation, (1) appointing additional examiners; (2) arranging that students shall not be examined orally in the presence of one examiner only; and (3) requiring from each candidate a certificate of instruction in clinical midwifery and gynæcology. The Committee recommended an early re-inspection of the examination in midwifery in this University.

Dr. Tooth had reported on the efficient teaching of and examination in pathology, which in certain of the universities was a part of the final examination. He did not apparently regard the position of pharmacology so favourably, and advised that more attention be devoted to the correct writing of prescriptions. A matter frequently referred to by the inspectors was the disregarding by certain of the licensing bodies of the recommendation of the Council (No. 7) that students should not be examined by one examiner alone. Most of the bodies into whose examination the practice had crept indicated in their remarks on the inspector's report that it would not occur in future. The strict acceptance of the Council's recommendation meant more examiners, but also meant better and fairer examination. The Committee urged that its importance be impressed on all the bodies.

Examination in Clinical Medicine.—The Committee noted that the time allotted to the candidate for the "long" or "commentary" case varied considerably, being three hours in several examinations, and ten minutes in one. The Committee was of opinion that it was very important to impress upon the student the necessity of careful and thorough examination of all patients; that at least an hour and a half should be devoted to this part of the examination; and that it considered that a recommendation to this effect should be made.

Evidence of Further Study after Rejection.—Recommendation 4, adopted by the Council, was as follows: "A candidate remitted in any subject should, before he is admitted to re-examination, be required to produce satisfactory evidence that he has pursued the study of that subject during the interval of remission." This recommendation had not been very closely observed by the bodies, which might partly explain cases referred to by the inspector on surgery of candidates appearing for the tenth time for examination. Incidentally on this recommendation another matter arose: in those bodies where examinations were held only twice yearly rejection necessarily involved a six months' period of further study, and no suggestion was made that the period need ever be longer than that; but those bodies who held more frequent examinations should be recommended to look more closely into the question of the period of further study, and instruct their examiners to pay greater attention to the regulations which in most cases exist.

Interchange of Examiners.—On collating the reports it was noted that the names of several examiners appeared in connexion with the examinations of more than one licensing body. Quite a number examine in two; three is not uncommon; and two, one in surgery and one in midwifery, examine in four. There was much to be said for a more general adoption of this plan; not only did it give the examiners greater experience, but it obviously tended to maintain a uniformity of method and an equality of standard such as is desired by those who advocated adoption of the one-portal system. Dr. Tooth had made the interesting suggestion that an interchange of visits of inspection should be arranged between representatives of all the universities and licensing bodies.

Marking.—Whatever the total figure—which varied from 55 in the English Conjoint to 1200 in the University of Manchester—the pass standard was almost invariably 50 per cent. of the maximum figure. It would assist the Council if the various examining boards would agree on a uniform system of marking, but it should be the universal practice that no one who was unable to obtain 50 per cent. in clinical medicine or clinical surgery should be admitted to the Medical Register. On the question of exemption, the Council's recommendation that a 60 per cent. mark should be required was not universally adopted; some bodies admitted to one subject at a time and gave a pass on a 50

Mellanby's opinion, as expressed in this monograph, tends to compromise between these extreme opinions. Thus an anti-rachitic factor, "probably identical with the fat-soluble vitamin," together with sufficient calcium and phosphorus in the diet, are considered factors of first importance in preventing rickets; meat and exercise assist in prevention. Restriction of any of the four factors named or excess of carbohydrate food promotes the development of rickets. These results agree well with clinical opinion and practice. The research emphasises the importance of a balanced diet and indicates that too much of one substance may be as harmful as too little of another. The work is being actively prosecuted, and the author states that the present publication is to be regarded as an interim report.

PLAGUE AND SMALL MAMMALS.

WE commented last week on Dr. L. G. Haydon's article (THE LANCET, Nov. 26th, p. 1103) which dealt with sporadic outbreaks of plague in South Africa, and drew freely upon information supplied to him by Dr. J. Alexander Mitchell, Secretary for Public Health and Chief Health Officer to the Union of South Africa. Dr. Mitchell has since sent us a copy of a paper, read by him at the South African Medical Congress in October, which deals fully with the fauna of the infected country, and includes an extremely valuable account of the fleas found on the various animals that have come under notice during these investigations. Dr. Mitchell lays particular emphasis on the fact that the human cases were nearly always infected from gerbilles; evidence of recent migration and desertion of gerbille burrows was obtained in a few instances, mummified carcases and skeletons actually being found, showing that the epizoötic was a severe one. Most of the plague cases occurred in the area frequented by the gerbille.

POIKILODERMA ATROPHICANS VASCULARE.

ACCORDING to Dr. John E. Lane [1] of New Haven, Connecticut, who reports a case under his care in a man aged 30, and another under the care of Dr. Oliver S. Ormsby, of Chicago, only 12 previous cases have been published, nine in German, two in French, and one in Russian literature, of the remarkable skin condition, described by E. Jacobi in 1906, under the name of poikiloderma atrophicans vasculare. Of the 14 cases on record, nine were males and five females. The youngest was 6 years of age, two were 41, and the rest between 20 and 33. In all the cases in which reference was made to it the Wassermann reaction was negative. In a few instances other diseases were associated with it, such as pulmonary tuberculosis, myositis, rheumatic or gouty manifestations, juvenile muscular atrophy, calcareous deposits, malaria, ichthyosis, and lymphosarcoma. The dermatosis usually begins in late youth or early adult life, is of very slow evolution, and of approximately symmetrical distribution. It is attended by mild pruritus and presents as its chief manifestations telangiéctasis, pigmentation, and later capillary hæmorrhages and atrophy. Histologically there are two stages, an inflammatory and an atrophic. The inflammatory stage is manifested by round-celled infiltration and dilatation of the superficial vessels and alternate increase and diminution or absence of pigment, while the atrophic stage is characterised by flattening of the papillæ, degeneration and disappearance of the elastic tissue, and atrophy of the collagen bundles. Poikiloderma has been variously classed as a disease *sui generis* (Jacobi), a toxic erythema (Ehrmann), lupus erythematosus (Kreibich and Arndt), atypical scleroderma (Jadassohn), and diffuse idiopathic atrophy (Darier, Brocq). The conditions for which poikiloderma may possibly be mistaken are Schamberg's progressive pigmentary disease, Majocchi's disease and generalised telangiectasia connected with syphilis. Nothing is known as to the ætiology, but it has been suggested that toxic bodies acting on the vessels and connective tissue may be factors in its causation, while the theory of an embryonic defect has been maintained by Glück and Bettmann.

CORONERS' JURIES AND THE L.C.C.

TWO pieces of war legislation which have proved of value under peace conditions were the Acts of 1917–18, governing the size and attendance of coroners' juries, and the London County Council is anxious to preserve both these measures as a permanent reform in the procedure of coroners' courts. The Coroners (Emergency Provisions) Act, 1917, provided that "seven" and "eleven" should be substituted for "twelve" and "twenty-three" as the minimum and maximum numbers of jurors summoned by a coroner to form a jury. The question of reducing the number of inquests held with a jury was dealt with by the Juries Act, 1918. Section 7 empowered a coroner to hold an inquest without a jury, if he was satisfied that it was proper to do so. He was prohibited from exercising this discretion in cases where (*a*) death occurred in prison, (*b*) death occurred in such circumstances as to require an inquest under an Act other than the Coroners Act, (*c*) there appeared to the coroner reason for summoning a jury or for suspecting that the deceased had come to his death by murder or manslaughter. Unless Parliament takes further steps both Acts will cease to operate on Feb. 28th, 1922. These war-time relaxations of the law had previously been advocated by the London County Council, and their working has afforded a large measure of relief to the community in the matter of jury service. For instance, the coroners' vouchers in three districts, over a limited period, show that out of 152 inquests no fewer than 140 were held without a jury. No complaint has been received and considerable financial saving has been effected. Before 1917, jurors' fees in the County of London amounted to more than £3000 a year, but this amount was reduced in 1919 to £533 10*s*. Moreover, in many cases of sudden deaths at infirmaries and hospitals, the coroners have been able to view the body at the place of death, thus saving the cost of its removal to a public mortuary. This course would not have been possible if a jury had been required to view the body. Acting on the recommendation of its Public Control Committee, the County Council has therefore decided, in the interests of economy and public convenience, to urge the Government to take steps to give permanent effect to these useful provisions.

THE SAFETY OF CHLORINATED WATER.

IT is unreasonable to expect tap-water to taste like lemonade, but it should, at least, not be nauseating. The rapid and careless way in which chlorination had to be carried out for troops on foreign service bred in many of them a permanent prejudice against any kind of "doped" water which has carried over into civil life. Of course, the sterilisation of water by means of chlorine long antedates the late war, and Sir Alexander Houston recounts the well-meant criticism directed against him in connexion with the chlorination of the water-supply at Lincoln as long ago as 1905. During the war chlorination secured its place as a universal method of making any doubtful sample of water safe for immediate use as a beverage, and a large part of London's water was treated in this way. The removal of the taste after sterilisation has been effected is now a simple matter, and was set out in a recent circular issued by the Ministry of Health. Prejudice being thus on the wane, little alarm was created in June last, either on the spot or in other countries having organised water-supplies, when a coroner's jury in Chester County, Pennsylvania, returned the sudden death of a local citizen as due to "general systemic debility caused by chemicalised water, which produced a severe gastroenteritis followed by cardiac failure." Pending the completion of new filters, the Pennsylvania Department of Health is prudently disinfecting its

[1] Archives of Dermatology and Syphilology, November, 1921.

4. That in the examination in clinical medicine at least an hour should be allowed for the examination by the candidate of his principal case.

5. That candidates who obtain very low marks should be remitted for further study for a longer period than three months.

6. That in the final examination candidates should either pass all three subjects (medicine, surgery, and midwifery) at one sitting or be required to complete the whole of the final examination within a period of 18 months.

7. That the recommendations of the Council on professional examinations be revised, and that they be circulated in draft to all the bodies for their consideration and observations.

Education Committee.

The adjourned consideration of the draft report was resumed; the following were its main proposals:—

Examinations in Great Britain.—The Council will recognise the undernoted university examinations subject to the conditions specified below: The University of Oxford—Responsions; the University of Cambridge—Previous Examination; and the Matriculation Examination of the Universities of London, Durham, Scotland, Manchester, Liverpool, Leeds, Sheffield, Birmingham, Wales, and Bristol.

The conditions prescribed by the Council are: (1) The standard of the examination shall not be lower than that of the University Matriculation Examinations in the Faculties of Arts and Pure Science; (2) the certificate shall bear evidence that the candidate has passed in the following subjects—viz.: (1) English; (2) mathematics, elementary or additional, or a science—(*a*) physics; (*b*) chemistry; (*c*) physics and chemistry; (3) a language other than English; (4) any other subject or subjects embraced in the official list of the examining university.

Subject to the conditions specified above (Section I.), the Council will recognise all examinations conducted by recognised authorities in Great Britain accepted by one or more of the above-named universities as equivalent for purposes of matriculation within the accepting university to an examination named in the preceding list (Section I.). The Council will continue to recognise examinations conducted by bodies other than those (referred to in Section II.) directly recognised by the universities of Great Britain. Recognition will not be extended under this section to any examination unless the Council is satisfied (1) that in scope and standard it is equivalent to a recognised examination of a British university, and (2) that it fulfils the conditions specified by the Council (Section I.).

Examinations in Ireland.—Subject to the specified conditions (Section I.) the Council will recognise the entrance examination of the University of Dublin, and the matriculation examinations of the National University of Ireland, the Queen's University of Belfast, and the Royal College of Physicians and Surgeons in Ireland, and all examinations accepted by one or more of these bodies as equivalent for purposes of entrance or matriculations to the above-named examinations.

Colonial Examinations.—Subject to the specified conditions (Section I.) the Council will recognise all examinations of Colonial universities which are accepted by one or other of the British universities as equivalent for purposes of matriculation within the accepting university to an examination named in the list of examinations recognised by the Council (Section I.).

Restoration of a Name to the Register.

The Committee, having considered an application from John Shaw for restoration of his name to the Register (from which it was removed at his own request in 1908), recommended to the General Council that the Registrar be directed to restore to the Medical Register the name of Dr. John Shaw; and having also considered the application for removal of name of Miss Lillie M. A. Jones, recommended that it be not acceded to, on the ground that the Executive Committee is not satisfied that she has ceased to practise. The Council adopted these recommendations.

This concluded the business of the session.

EPSOM COLLEGE.—The Council of the College will shortly be awarding "France" pensions of £30 a year to medical men not under 55 years of age, whose income, independently of any allowance from the College, does not exceed £100 a year. Forms of application can be obtained from the secretary, Mr. J. Bernard Lamb, at 49, Bedford-square, London, W.C. 1.

A REPORT ON DIPHTHERIA.[1]

A PRELIMINARY note addressed to Sir GEORGE NEWMAN, Chief Medical Officer of the Ministry of Health, prefaces a report upon diphtheria made to the Ministry by Dr. MONCKTON COPEMAN, F.R.S. The note is written by Dr. G. S. BUCHANAN, C.B., Senior Medical Officer, Ministry of Health, and runs as follows:—

1.—*Schick Test and Active Immunisation Against Diphtheria.*

The report herewith submitted deals, *inter alia*, with the use of the Schick test as a means of recognising susceptibility to diphtheria, and with the method of conferring immunity, by means of inoculations of a standardised toxin-antitoxin mixture, on those who have been found to be susceptible to diphtheria by this test, or are assumed to be susceptible on other grounds. This system of diptheria prevention has been adopted on an extensive scale in New York, where prevalence of diphtheria has been greater and the mortality from this disease considerably higher than in this country. The object of its adoption is not the separation from the population of infective cases and carriers; it is assumed that risk of infection from such cases must always be considerable and to a large extent beyond control, and it is consequently considered preferable to adopt a method which secures a substantial immunity of the general population concerned, or at least of a large part of it. In order that this may be obtained on a sufficient scale, the New York system provides a medical service for carrying out the testing and immunising, especially in the school population. Steps are also taken to obtain the coöperation of medical practitioners who apply the Schick test, and where necessary undertake the immunisation, with material supplied to them from the New York State laboratories.

In his report Dr. Copeman has collected and set out some of the principal considerations and data regarding the Schick test and methods of immunising against diphtheria. With this he has combined the results of personal observations of these methods from his experience at Bristol and that of several collaborators, particularly Dr. D. S. Davies, Prof. Walker Hall, Dr. Nixon, and Dr. Norgate at Bristol, and Dr. O'Brien of the Wellcome Laboratories.

The observations on this subject in the report will, it is anticipated, be useful to medical officers of health and hospital and school medical officers who have specially to deal with diphtheria outbreaks in this country. It would be premature to advise that in English communities general immunisation of persons susceptible to diphtheria should be attempted on the New York scale. More information and experience would be necessary before this could be recommended, and it would be necessary to be satisfied that equally good results cannot be obtained by extension and improvement of the methods of diphtheria prevention on which we rely at present. At the same time, there are already circumstances in which the evidence available may be considered to warrant a trial of the Schick reaction and toxin-antitoxin immunisation. For example, a parent who for one or another cause is specially anxious that his child should avoid all possible risk of contracting diphtheria, may ask whether medical science cannot now provide a means by which the degree of the child's susceptibility can be estimated, and by which, if the susceptibility is great, the child can be protected for at least some years without any substantial risk, and with at most only a transient and insignificant disturbance of health, as the result of the inoculation. A similar question may be asked by nurses and others likely to come much into contact with diphtheria cases, or again by medical officers of residential schools and other limited communities at a time when diphtheria is epidemic. The information now available—much of which is epitomised in Dr. Copeman's report—shows that there is good warrant for an affirmative answer to such questions.

The technique of the Schick test is comparatively simple, though, like all scientific methods, it requires some little experience before the observer can have confidence in himself and in his interpretation of the reactions obtained. Its essential points are now fully described in medical literature and some practical suggestions—especially as to control inoculations with heated toxin—are set out in this report. Demonstrations of the test might readily be given (if they are not given already) at post-graduate courses or during the instruction on infectious diseases which forms part of the curriculum of medical students.

The immunising treatment is obtained by a series of simple inoculations. The necessary toxin-antitoxin mixture (as also the toxin required for the Schick test) is, in New York, support of his position he quotes many impressive statistics from the experience of the army. But the value of his statistical evidence is seriously impaired by the fact that all of it deals with men under discipline. The casual civilian is hardly likely to carry out self-disinfection with anything like the thoroughness of the soldier—who, in addition to a suitable opportunity for self-disinfection in an "ablution hut," has a lively knowledge from the "exhortations" he has heard of the seriousness of venereal disease. In the matter of statistical evidence, however, Sir Archdall Reid is effectively countered by new facts put forward by Dr. Otto May, who makes use of figures quoted by Prof. Galewsky at the North European Red Cross Regional Conference on Venereal Diseases held in May at Copenhagen. In Germany, methods of self-disinfection have been taught with German thoroughness, and prophylactic agents of the recognised kind are easily procurable. The figures speak for themselves. In Dresden in 1919 14 boys and 60 girls between the ages of 14 and 18 attended Galewsky's Venereal Clinic for treatment. In 1920 there were 105 boys and 116 girls between the same ages, and in the first three months of 1921 the figures were: boys, 33; girls, 61. One must be careful in deducing conclusions from statistics, but these figures are very significant. Further, Dr. Otto May quotes figures from a certain London clinic which show that of 375 infected men who came for treatment 101 stated that they had used chemical disinfectants after exposure.

---

[1] Report on Diphtheria to the Ministry of Health. London: His Majesty's Stationery Office. 1921. 9*d*.

Any medical man actively engaged in the treatment of venereal disease can cite cases where "disinfection" immediately after intercourse has failed to prevent disease. It is often said that morality based on fear is a poor kind of morality, but surely it is better than immorality encouraged by a false sense of security. May we suggest to Sir Archdall Reid and Dr. Otto May and the societies they represent that, with this week's great political example before them, they declare a truce to all wordy warfare and devote the next 12 months to collecting evidence from the medical officers in charge of 100 of the larger V.D. clinics on these two points: 1. What proportion of patients attending with fresh infections used disinfecting agents (and if so, what) (*a*) before intercourse, and (*b*) immediately after intercourse. 2. To what extent does the use of calomel ointment or other mercurial immediately before or immediately after intercourse delay the appearance of, or modify the characters of, the primary sore. If incomplete "disinfection" makes a primary sore atypical it may lead to delay in the institution of proper treatment, and so bring about disaster. Reliable evidence as to these points would do more to enable the man with an open mind to come to a right decision in this vexed question than any of the arguments that have hitherto been advanced.

AN important conference upon serological problems will take place in London on Monday, Dec. 12th, and following days. The conference has been convened by the Health Committee of the League of Nations and will meet under the presidency of Prof. Th. Madsen, Director of the State Serological Institute of Denmark, who is the president of that Committee. Distinguished workers from laboratories in the following countries will attend the conference: Austria, Belgium, Denmark, France, Germany, Great Britain, Italy, Japan, Poland, and Switzerland. It is hoped that the President of the Office International d'Hygiène Publique and an American representative will also be present. The British delegates will be nominated by the Medical Research Council. By the courtesy of the Government the meetings will take place at the Ministry of Health. The conference will be occupied with a consideration of existing methods of standardising sera and the possibilities of attaining an agreed international system of serological standards. It will also take count of the methods used in leading laboratories for the serum diagnosis of syphilis. Arrangements for new investigations will be discussed.

GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

(*Concluded.*)

FRIDAY, NOV, 25TH.

Pharmacopœia Committee.

The **PRESIDENT**, as chairman of the Committee, presented the report to the Council. The number of copies of the British Pharmacopœia, 1914, sold by the publishers between May 21st, 1921, and Nov. 19th, 1921, was 1427. The number sold in the year ending Nov. 19th, 1921, was therefore 2407. The total number sold since the date of publication was 41,385. The stock in hand was sufficient to meet the present demand for some time to come. On behalf of the Committee, Sir Nestor Tirard and Prof. Greenish, as editors of the British Pharmacopœia, 1914, had attended a conference called by the authorities of the National Physical Laboratory to consider the question of the official testing and marking of glassware used for purposes of measurement. It was understood that, as a result of the conference, an advisory committee is likely to be set up, on which the General Medical Council would have representation. It was desirable that some of the difficulties in respect of the standardisation of measuring vessels, indicated in the preface to the British Pharmacopœia, 1914, should be considered and, if possible, obviated before the next revision of the work. A cordial offer of coöperation with the Committee in matters of common pharmacopœial interest had been received from the chairman of the Committee of Revision of the Pharmacopœia of the United States of America, 1920–30. The Committee had, on behalf of the Council, welcomed the offer warmly and accepted it, being assured that such coöperation cannot but be of the greatest importance, both in the interest of the respective Pharmacopœias and in that of international comity and friendship.

Students' Registration Committee.

Sir **NORMAN MOORE**, chairman of the Committee, presented this report to the Council. The report was adopted. Various applications for exceptional registration or antedating of the commencement of professional study had been considered by the Committee and were made the subjects of recommendation in the report. The following institutions, having applied for the approval of the Council, and satisfactory evidence as to their visitation having been shown, were added to the list of those recognised by a licensing body and approved by the Council: Burnley: Municipal College; Cheltenham: Dean Close School; Ipswich: High School; London: North London Collegiate School; Streatham Hill High School; Wimbledon High School; Shrewsbury: Shrewsbury School.

Education Committee.

Dr. **MACKAY**, chairman of the Committee, made an oral interim report to the effect that the work of the Curriculum Committee was going on in a very satisfactory manner. Four English subcommittees had been reported, and a conjoint report had been presented; in the case of Scotland and Ireland, the conjoint stage had not been reached. He proposed that the final reports of all the committees when completed should be printed and circulated among all the members of all the committees; that any further comments by members of the committee on proposals submitted by other committees should be transmitted at as early a date as possible to himself; and that he should then arrange for a joint meeting of all chairmen of committees, with the object of arranging for due consideration of the changes; that thereafter all the reports along with the comments thereon made by the chairmen be transmitted to the Education Committee, which should then prepare a general statement for the consideration of the Council at its next meeting in May, 1922. The President was a normal throat. Exceptional instances are on record of healthy persons with apparently normal throats and no nasal discharge acting for long periods of time as carriers, and some degree of security against these rare cases may be obtained by the routine swabbing recommended in the Memorandum on Exclusion from School, 1909, which requires negative reports from three successive swabs taken on separate days as a condition of the return of the child. But even this proceeding cannot be relied upon for the certain and automatic detection of such cases, and, as already indicated, a positive result may only mean the presence of a non-virulent bacillus, which does not justify exclusion from school. In Prussia such considerations as these have led to the arbitrary solution that, for the present, no diphtheria carrier, if otherwise healthy, is to be excluded from school longer than eight weeks after clinical recovery (Ministerial Circular of April 11th, 1921).

(c) *Routine Swabbing in Outbreaks of Diphtheria in Schools and Institutions.*—This practice would seem to be chiefly useful on the first appearance of cases of diphtheria in the school or class. A class, the members of which have been but slightly exposed to an initial infection, may, by means of swabbing, be pronounced with reasonable confidence to be free from carriers. Or the system may succeed in detecting one or more other children whose throats or noses are infected and so lead to their isolation and the clearing of the class, for the time being, from all carriers. At a later stage, however, and particularly in day schools, it would seem that the spread of the carrier condition (as distinct from actual diphtheria) often becomes extensive, and at this stage systematic swabbing, producing large numbers of positive results, affords little guide for useful practical action. Negative bacteriological results in such cases may be consistent with intermittences in a chronic carrier condition. In such circumstances it seems better to concentrate on the clinical condition of the children, and the temporary exclusion from school of those showing signs of chronic sore-throat and nasal discharge, while at the same time using bacteriological methods principally for the determination of the nature of these particular cases. The practice in the London County Council schools has now come to be based largely on these considerations.

Numerous observations are being made on questions such as those on which I have touched. It is to be hoped that, by their active continuance both in the laboratory and in the field, it may before long be possible to obtain scientific authority for something like a definite code for the effective prevention of the spread of diphtheria, such, for example, as we may be said now to possess in the case of enteric fever or small-pox. At the Ministry every effort is being made to follow the development of the subject. Medical officers of health and medical officers of schools and isolation hospitals can, in this connexion, do a specially valuable service if they will communicate to the Ministry, in the form of special reports or otherwise, the results of preventive measures which they test, and the views which they have been able to form in regard either to the extension or to the simplification of the methods of which they have had experience.

MEDICINE AND THE LAW.

Landru.

Henri Désiré Landru has been found guilty at Versailles and sentenced to death for the murder of 10 women and a youth. The jury, who convicted him "without extenuating circumstances," immediately signed a document in his favour. There will be an appeal, and the last has not been heard of a case which has already dragged on for some years.

It was proved as clearly as possible, in the absence of eye-witnesses, that Landru killed his victims at his villa at Gambais, and did away with their remains by burning them in a stove. This rough-and-ready form of cremation owed its success to the house being isolated by a garden, and to the murderer being able to conduct his activities at his leisure. There was, however, the evidence of neighbours as to unusual smoke and odours. Further, the state of the stove, which was new when Landru first occupied his house, indicated that excessive use had been made of it. His counsel's appeal to a higher court on his behalf will probably be based largely upon the non-discovery of ascertainable portions of the bodies of any of the victims named in the indictment. This may have influenced the jury in endorsing the claim for a reprieve, who may also have felt a doubt as to Landru's sanity. As to this, Landru in all reasonable probability would have been convicted in England in far less time than his case has occupied in France, and would not have been found "guilty but insane." In whatever way the gaps in the story of his crimes are filled up, he can hardly be conceived as not knowing the nature and quality of his acts when he committed them, and not knowing that they were wrong.

Some measure of mental abnormality, no doubt, may be assigned as partly responsible for a series of crimes almost without parallel in the records of civilisation. This was evidently the impression conveyed to Sir William Orpen, R.A., whose account of a day in the Versailles court appeared in the *Evening Standard*, with a graphic sketch of the murderer's head. Sir William Orpen writes:—

> "Having seen him I cannot believe that if he murdered those poor people he ever did it in cold blood for the paltry sums of money it has been proved he received from their disappearance or murders. No, it must have been sensual blood lust which caught him at times and made him mad, after which he returned to his normal, kind, contented humdrum life until the madness took him again."

This expression of belief in an impulse beyond the murderer's control is interesting as coming from a layman, but it is subject to the observation that Landru coolly and cunningly provided himself with a series of victims by similar methods in every case, and having found a way of dealing with the bodies which promised immunity from discovery pursued it methodically. In this he resembles the pair of murderers whose names are most familiar to us in this country, and whose case in other respects may be compared with his. With him and with them ultimate discovery was practically certain. He and they persevered until they were caught. The story of Burke and Hare has recently been related here, and in many lay journals, and it forms the latest volume of "Famous British Trials," but the resemblance to Landru's story may be pointed out. Burke and Hare found that Knox, an anatomy teacher, required bodies for his anatomical school and was ready to pay £10 apiece for them and to ask no questions. Dissected bodies could not be reassembled for identification, and there was comparative safety when once they were disposed of. Burke and Hare certainly murdered for profit, and although Landru's booty may not have been large in our eyes, he took care to secure it. Burke and Hare, like Landru, preyed upon a class whose members are apt to disappear without inquiry being made as to their absence. They, however, included men with women among their victims, and lust was not an element in their crimes. Landru's apparent advantage lay in the fact that a woman before going to live with him as his wife or mistress, probably prepared her friends, if she had any, for her prolonged absence, and in outwardly favourable circumstances left a home at some distance before dying in the "accursed villa," as the prosecuting counsel called it. Women who become the mistresses of men of his class, besides being birds of passage, would not correspond with their relatives.

Rex v. Starkie.

The Court of Criminal Appeal has dismissed the appeal of Dr. R. W. Starkie against his conviction and sentence at the Central Criminal Court to nine months' imprisonment. The principal ground of the appeal was the trying together upon one indictment the charge of administering drugs with the intent to procure miscarriage, and charges alleging the use of instruments for the same purpose. It was also argued that in his summing up Mr. Justice Acton ought to have directed the jury expressly that in considering their verdict upon the count relating to drugs, they must ignore all evidence given before them on the other charges. Sir Richard Muir replied per cent. mark therein. It had been suggested that this practice was growing; it was clearly contrary to the recommendations of the Council.

Unity of Final Examination.—The inspectors on medicine and surgery, the latter in more forcible terms than the former, both advocated that candidates should either pass all three subjects (medicine, surgery, and midwifery) at one sitting, or that, if exemption in single subjects were permitted, candidates should be required to complete the whole examination within some prescribed period. The inspector on medicine admitted that, in those bodies which included pathology, pharmacology, forensic medicine, and hygiene in their final examination, the burden on the candidate would be heavy, and he suggested that the bodies which followed this plan might adopt the one generally followed elsewhere, and arrange for a pre-final examination in these subjects. The Committee agreed to recommend to the Council that it should be a recommendation to the bodies that the final examination in the three subjects of medicine, surgery, and midwifery should be completed within a period of 18 months. The Committee thought that the separation of the examination in clinical medicine and clinical surgery from the systematic parts of the examinations in these subjects is inadmissible.

Mental Diseases.—Several of the bodies did not profess to include this subject; others included one or two questions in the medicine paper; in others it appeared in the syllabus. Liverpool and Bristol had a separate paper on the subject, and Durham, Dublin, and Birmingham each held a clinical examination.

Diseases of Eye, Ear, and Throat.—The inspectors in medicine and surgery recommended that candidates' knowledge of these diseases should either be efficiently tested in the final examination, or should produce evidence that they had been sufficiently instructed and tested as to their knowledge of these subjects.

There was considerable discussion of the body of the report, several members of the Council expressing their satisfaction at the Committee's mention of the advantage to students of examination by two examiners sitting together rather than by a single examiner.

Sir Arthur Chance, referring to the fact that in the inspector's detailed consideration of examinations the words "no questions on mental diseases were put" occurred in the note on the Irish Conjoint Board, said that if mental diseases were admitted then such subjects as ophthalmology would also have to be included, and examination on the three main subjects of medicine, surgery, and midwifery would be lengthened and weakened.

Sir Francis Champneys pointed out that the inspection of examinations was not yet normal or fully recovered from the conditions imposed by the war. With regard to a clinical examination in midwifery, this was impossible to obtain in some places. Examining bodies had no control over the material. The difficult and essential things to teach were diagnosis and treatment of abnormal labour; clinical examination of ordinary cases would not give what was required. Fixed dates for examination were impossible in this connexion; a student should be taught manipulation and diagnosis in the course of his work, and strictly certificated by his instructor for purposes of examination.

Sir James Hodsdon, after referring to the difficulty of clinical examination in obstetrics and the importance of proper preparation of students for examinations, said that with reference to the system of marking the examiner's question to himself must not be "does this candidate deserve 50 or 60 per cent.?" but "is this candidate fitted to pass the examination?" He favoured the unity of the final examination, believing that a candidate tended to neglect further study of the subjects he had passed in. Only five licensing bodies at present required students to pass medicine, surgery, and midwifery at one time.

Dr. T. W. Griffith said that it would injure the final examination to insist on pre-final special tests; it was well for students to expect examination in all parts of medicine.

Sir Gilbert Barling pointed out that a candidate who failed several times in only one of three subjects was practically condemned to seek another career. He wished the Council to bear in mind that a new curriculum was being prepared, and supported the plan of certification of students in clinical midwifery.

Sir Sydney Russell-Wells expressed satisfaction that the Council was agreed concerning the wisdom of having two examiners sitting at a time, and spoke of the financial difficulty in this respect.

Mr. Waring stated that he had found the percentage method of marking more satisfactory than any other, and emphasised the importance of making students familiar with methods of examination in ophthalmology, oto-rhino-laryngology, &c.

Sir John Moore pointed out that with regard to the examination of the Irish Conjoint Board, the inspector had been rather hard on that body; he had merely come upon an examination in which mental disease happened not to be the subject of a question.

Prof. Littlejohn regretted that the Council had never indicated at what period in a student's career he should be taught forensic medicine and public health subjects.

Sir Jenner Verrall advised the Council not to be too much concerned with the convenience of examining bodies, and also emphasised the importance of examination by two examiners.

Dr. Macdonald hoped that no discouragement would be cast upon any attempt to better the teaching of clinical medicine; midwifery was at present a disgrace to the profession.

Mr. Turner pointed out that in the reports of all the papers given during the examinations inspected only two questions had dealt with venereal disease. At present the ordinary medical qualification did not permit a practitioner to obtain free material from the Government for treatment of these diseases; post-graduate evidence of knowledge was required by the authorities. The older generation was past praying for; the only hope in this matter was to equip the coming general practitioners thoroughly in this respect.

Sir Edward Coey-Bigger remarked that the death-rate among midwifery cases was practically at a standstill, that something—in his opinion the teaching of the subject—was radically wrong, and more midwifery hospitals were needed.

Dr. McVail agreed with Prof. Littlejohn that it was difficult to discuss the report before the report on the new curriculum had been issued. He had not noted much reference in the report to the machinery of examination. An early "block" should be provided so that a student could not go through the early subjects only to fail repeatedly at a later stage.

Dr. Norman Walker answered various points which had arisen, and claimed that although the Examination and Education Committees might seem to interfere with one another in the matter of the curriculum, of which the report had not yet been issued, yet it would be a pity to hold up their work on that account. The clinical examination in midwifery was very easy in some places, very difficult in others, but improvement might be secured if the licensing bodies could be made to feel that the Council were serious with regard to this matter. He then presented the following recommendations of the Examination Committee, which were adopted by the Council:—

1. That the attention of those bodies who do not hold a clinical examination in midwifery and gynæcology should be drawn to the importance of observing No. 19 of the Council's recommendations.[1]

2. That the President be requested to arrange for a re-inspection of the examination in midwifery in London University at an early date.

3. That the importance of observing Recommendation 7—viz.: "A candidate should not be orally examined except in the presence of two examiners," should be impressed on all the bodies.

---

[1] Recommendations of the General Medical Council concerning Professional Examination, adopted June 9th, 1896, May 30th, 1907, and Nov. 26th, 1909, of which No. 19 reads as follows: "The final examination should include clinical and practical examinations in midwifery and gynæcology."

accommodation for nurses was urgently needed. A trust estate which had been left to accumulate for 14 years was now available for convalescents of the infirmary, the sum amounting to £600,000. The new home would be used for patients who could not walk.

Dec. 5th.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

A New Biological Station in the Austrian Alps.

A PRIVATE benefactor has enabled the Vienna biological station to establish a new laboratory and organise an up-to-date research station on the Mondsee, a lake near Salzburg. The research station was at first situated in Vienna and later at Trieste, where its chief activity was the study of the fauna and flora of the Adriatic. With the breakdown of the Austrian Empire it was transferred to the Lake of Luntz in Upper Austria, but there the water proved too cold; it had, moreover, to be utilised for the supply of power to factories. On the Mondsee all conditions for continuation of research are to be found; the lake is warm (average temperature about 17° C.) and of great depth (187 metres), containing a large quantity of water, and having a fairly uniform climate. It is conveniently near university cities, being midway between Vienna, Innsbruck, and Munich. It may be recalled that Prof. Steinach's researches on rejuvenation were carried out at the biological station.

Sunshine and Health.

September was the healthiest month on record since the year 1912, owing no doubt to the uninterrupted sunshine experienced for over 250 hours during that period. Nevertheless, the population continued to diminish; the number of deaths was 1937, whilst 1915 living children were born. In July and August there was a small excess of births, but the number of cases of infectious diseases and the general morbidity were higher than in the corresponding period of the previous year. October was also a very healthy month, with a marked absence of all catarrhal conditions, generally prevalent at that time of the year. Sick-clubs and hospitals experienced beneficial effects from the prolonged summer weather; club balance-sheets showed unusually low figures for sick-pay and hospital accommodation of insured members declined. Some improvements were also noted in the health of patients at the children's clinic, at the lupus institute, and in the hospital for war cripples.

Sporotrichosis in Children.

At a recent meeting of the Vienna Medical Society Dr. König exhibited three patients, aged 10, 5, and 7 years, who had long been suffering from pathological conditions diagnosed as tuberculous. The oldest child, a boy, had had a swollen knee-joint for more than a year, had received all the regular treatments, and was able to walk again, but suffered a relapse; several livid-coloured foci in the vicinity of the knee then appeared, and thin discharge from a fistula was noted. In this condition the patient was brought to the clinic where the Pirquet and Wassermann tests proved negative. A diagnosis of tuberculosis was nevertheless made, and by chance, during operation on the joint, there were found a few reddish corpuscles, which on microscopic examination showed distinct sporulation. Thereupon large doses of iodine were given, with very good results. In the other cases, also, a diagnosis of tuberculosis was made elsewhere; there, too, the Wassermann and Pirquet's tests were negative, and the appearance of the affected region—hip-joint—was significant of tuberculous disease. Only after protracted observations was it possible to determine the presence of sporotrichosis. In a third case, a girl of 7 years, who suffered from kerato-conjunctivitis combined with painful inflammatory changes of the hip- and malleolus joint, a diagnosis of tuberculous affection was out of the question. Here again Pirquet's and Wassermann's tests were negative, and antirheumatic treatment was of no use, but iodine proved useful. Dr. König pointed out that a number of similar cases could doubtless be found, where the symptoms were similar to tuberculosis or syphilis but where both tests were negative, so that other ætiological factors must be suspected—sporotrichosis or actinomycosis. In the discussion which ensued, several competent observers agreed that in a number of cases alleged tuberculous disease of joints or bones did not run the accustomed course or respond to routine treatment. In such cases iodides nearly always gave excellent results.

Sixtieth Birthday of Prof. Hayek.

On Nov. 25th Prof. Hayek, the well-known director of the laryngological clinic, received numerous compliments on the occasion of his sixtieth birthday. His former and present assistants and numbers of his pupils assembled at the clinic, together with representatives of learned societies from Germany, Switzerland, Italy, Argentina, Uruguay, and Japan. One of the chief features of the celebration was the presentation to the well-known rhinologist of a remarkable Festschrift, a volume of 800 pages containing 74 original papers on rhinology, collected in honour of Hayek's contributions to professional knowledge. Since Hayek has been at the head of the clinic he has made it a centre of investigation of the physiology of the nose, throat, and trachea. A number of important researches on the pathology of the voice, the radical operations of cancer of the larynx, and the restitution of function of the upper respiratory organs have been originated.

Prolonged Dispute between Sick Clubs and their Physicians and Pharmacists.

For more than a fortnight the doctors of the Krankenkassa—which comprises chiefly factory employees, day-labourers, and artisans—have, after due notice, refused to treat these patients as members of the sick-club, regarding them as private patients, and making the same charges to them as to their regular private patients. The doctors demanded equalisation of their pay with that of other club officials, and upon refusal of their demand declared a medical strike. The pharmacists have also cancelled their arrangements with these clubs, refusing to dispense prescriptions to them at reduced rates. Over 250,000 persons are affected by the strike; the club is bound by law to provide medical help for its members in case of illness, so that the members try to recover the costs of medical attendance from the clubs. The Board of Health is endeavouring to reconcile the three parties; the club doctors have the support of the entire profession, and there is hardly a doubt that they will gain their point. The outcome of the conflict is watched with close interest by the entire profession; success in this connexion will stiffen the resistance of the doctors in the struggle with the Government, which is rendered inevitable by the present trend of legislation. The promises exacted from the Government by the 4-hours strike in the early spring of this year have hitherto remained on paper. Preparations are therefore being made to force the Government to comply with the reasonable demands of the medical profession.

Nov. 25th.

TROPICAL DISEASES LIBRARY.—Since the removal of the Tropical Diseases Bureau to the buildings occupied by the London School of Tropical Medicine the libraries of the two institutions have been united. The common library, which is known as the Tropical Diseases Library, is administered by a committee representing both institutions as well as the Seamen's Hospital Society, who are the trustees. The aim of the Tropical Diseases Library is to promote the study of tropical medicine and hygiene; the library and reading room are open daily from 9 A.M. to 6.30 P.M. (Saturdays 9 A.M. to noon) to all members of the profession who are interested in those subjects.

distributed on a large scale from State and other recognised laboratories, the authorities of which guarantee the uniformity of the constituent elements and of the mixture. Corresponding supplies in this country have hitherto been obtainable from the Wellcome Laboratory, and no doubt bacteriologists at other laboratories who are experienced in this type of work can furnish the protective material prepared according to the generally accepted standards. No officially standardised supply is issued by our public authorities.

It is important to note that the constitutional reaction produced by the immunising mixture may exceptionally be somewhat severe, particularly in adults and in those who, in response to the Schick test, show a positive combined with a strong "pseudo" reaction. Dr. Copeman's experience in this matter is referred to on pages 22 and 23 of his report. This consideration, however, need not prevent the use of the immunisation method, especially when regard is had to the much more formidable results of an attack of diphtheria. But, in the adult especially, it is advisable to meet the possibility by commencing inoculation with a minimal dose—say, 0·01 c.cm.—which is unlikely to cause any trouble even in susceptible individuals.

2.—*Customary Methods of Control of Diphtheria.*

Dr. Copeman also makes some observations in his report on the general question of dealing with diphtheria carriers and on other matters which bear on the methods of control of diphtheria which are customary in this country.

This question has recently received much attention from various sides, particularly in consequence of the increased epidemicity of diphtheria in certain districts of England, including London, during the past few years. In connexion with this the medical officers concerned with the matter at the Ministry have had the benefit of frequent exchange of views with medical officers of health, medical officers of infectious diseases hospitals, and bacteriologists, including members of the Committee of the Medical Research Council which is studying bacteriological standards, and a committee of the Epidemiological Section of the Royal Society of Medicine.

In essence, the chief difficulty in the choice of appropriate methods of prevention lies in assessing the infective ability of the different individuals who collectively are classed as "carriers" of the diphtheria bacillus. The fact that this bacillus, when present in the mucous membrane of throat or nose, can be recovered and identified by swabbing and transmitting the swab to the bacteriologist, was established many years ago; first for those suffering from clinical diphtheria, and afterwards for the convalescent and for the healthy person who harbours the bacillus for longer or shorter periods without any ill-results to himself. In its original medical application, and in methods of public health administration based upon it, the simple procedure of swabbing and awaiting a positive or negative opinion from a bacteriologist seemed almost self-sufficient. The bacteriologist's report on the swab determined the diagnosis of the case; persons believed to have been closely in contact with the case were also swabbed; a negative finding would be considered as for practical purposes evidence of absence of danger, while any positive finding demanded all available precautions, time, and patience, until at length one or more reports on subsequent swabs happily proved to be negative.

These earlier and simpler conceptions have now in large measure been abandoned with the growth of knowledge as to the frequency of the carrier condition (in other diseases as well as in diphtheria) and of the very definite distinction which we have now to make between virulent and non-virulent diphtheria bacilli, although these are morphologically and culturally indistinguishable. Moreover, it is generally realised that, in practice, the results of swabbing are materially affected both by the thoroughness of the swabbing itself and by the method of examination and reporting which is followed in the laboratory. In all these circumstances it is important not to attach undue importance to a ritual of routine bacteriological examinations and reports, and not to regard such examinations and reports (as usually obtained in present practice) as the one and only basis of preventive action against diphtheria.

Observations may here be made on the following points, which frequently arise one way or another in practice.

(*a*) *Notifiable Diphtheria.*—The notification of cases of diphtheria under the Infectious Diseases (Notification) Acts should be limited to persons actually suffering from diphtheria—i.e., those exhibiting clinical signs of the disease, with or without bacteriological evidence of the presence of diphtheria bacilli. In the practice of some districts and of many medical practitioners, including, often, the medical officers of hospitals and residential schools, notification is frequently extended to include diphtheria carriers who themselves present no sign of illness. It is doubtful whether this practice is justifiable. Statistically it leads to much confusion; indeed, comparisons between diphtheria notification rates in different areas and in different parts of the country have for some years been rendered very unreliable by reason of uncertainty in this respect. Administratively, the effect may be equally unsatisfactory. The healthy carrier, as a result of his notification as a victim of diphtheria, is frequently removed to hospital where he may stay to the exclusion of persons urgently requiring treatment (a matter of great importance during the stress of an epidemic) and at unnecessary cost to the public authorities. Further inquiry and consideration might have shown that no benefit to the community or to the individual was likely to result from his segregation. A child attending school, for example, who is found to be a carrier, may merely have acquired that condition in common with the majority of the other children in his class at a time when diphtheria infection has been prevalent in the school for many months, and himself have no signs of illness; his bacilli may be non-virulent, and consequently he does not in all probability constitute a danger to others. Non-virulent diphtheria bacilli are not known to be capable of changing into virulent organisms.

It is no doubt of assistance to the medical officer of health, as a guide to preventive measures, to be informed of the result of the swabbing of any person in his district who is suspected to have diphtheria or to be a diphtheria carrier. But as the notification of cases which do not present clinical evidence of diphtheria cannot be required under the Infectious Diseases (Notification) Acts, arrangements should be made to obtain information in regard to such cases without relying upon the machinery of notification. Any local authority may incur necessary expenditure in arranging with practitioners in the district for the supply of such information relating to carriers as may be needed to enable the authority and its officers to carry out their duties under the Public Health Acts.

(*b*) *Antitoxin Treatment.*—Attention should be called to one circumstance in which substantial danger may result from depending too exclusively on bacteriological results. This is the case of antitoxin treatment, which should be begun at once when the clinical evidence of diphtheria is definite. Dr. F. Thomson and other experienced medical officers have recently insisted on the unsatisfactory results of the delay which is caused by the medical attendant having waited for a report on swabs sent to the bacteriologist before administering antitoxin.

(*c*) *Fitness for Discharge from Hospital.*—There is considerable divergence in the practice of different infectious disease hospitals as to the extent to which diphtheria convalescents are bacteriologically examined before being sent to their homes. If abundance of bacteriological assistance were available, including ample opportunities for applying tests for virulence, it would no doubt be desirable to follow a general rule that no case should be discharged until a sufficient number of examinations has been made to establish a very high degree of probability that the convalescent has ceased to harbour diphtheria bacilli; or that, if he is still a carrier, the organisms concerned are non-virulent. In practice, however, these conditions can seldom be realised, and the choice lies between obtaining a much more imperfect degree of information from routine swabbing, without virulence tests, and discharging the ordinary cases, when clinically convalescent, without any appeal to bacteriological findings.

There is little doubt that the necessity for routine bacteriological examinations can be materially lessened by due attention to the re-establishment of normal conditions in the throat and nose before the patient is discharged. The removal of enlarged tonsils, adenoids, &c., has been shown to be of particular importance and to form in itself a powerful method of reducing the numbers of infective carrier cases after diphtheria.

The experience in regard to return cases of certain Metropolitan Asylums Board hospitals in which no routine bacteriological examinations of discharged convalescents are made, seems to show that the return of convalescents to their homes in an infectious condition may be avoided with as much success as that obtained by those hospitals which adopt the rule that two or more negative swabbings must be obtained before the discharge of the patient is permitted.

In general, perhaps, it may be advised that when the bacteriological resources at the disposal of a hospital are limited, they will best be utilised for purposes of diagnosis of doubtful cases, and, with regard to convalescents, for those showing chronic nasal discharge or chronic sore-throat, the nature of which requires special investigation from the carrier point of view. In such instances it is always desirable that the laboratory should be in a position to follow up any positive results by virulence tests. Some recently suggested methods for simplifying these tests are referred to by Dr. Copeman on page 29.

(*d*) *Return of Diphtheria Convalescents to School.*—Somewhat similar considerations here apply. The risk of return of a virulent carrier may be greatly lessened, without recourse to bacteriological tests, by making sure that the convalescent is clinically recovered, is free from nasal discharge, and has human being (and after all, Mr. Peacock is very human) to furnish the information required. The vast majority of the thousand or more medical officers of the Second Army who were placed in medical charge of troops (and in whose capacity I wish Mr. Peacock could have higher faith) were accustomed to live in intimate contact with their brother combatant officers and shared alike in that intimate knowledge and sense of responsibility for their men which it has always been their pride to maintain.

I am, Sir, yours faithfully,
M. COPLANS.

The Jenner Institute Laboratory, Church-road,
Battersea, Nov. 30th, 1921.

FASTING.

To the Editor of THE LANCET.

SIR,—By his interesting and instructive article which appeared in THE LANCET of Dec. 3rd, Sir Henry Lunn has rendered a great service to the profession in redirecting attention to the therapeutic value of fasting. Pray permit me to support his thesis and offer a few comments. When the Allen starvation treatment for diabetes was first introduced, I tried it on several patients in my wards, and was more than satisfied with the results. The first patient, to whom I suggested it in private, was a semitic looking gentleman who claimed an ancient Scottish lineage. He irradiated a characteristic atmosphere of good temper and good living. When I had finished my recital of the benefits of a three days' fast, he became as if deflated; his face assumed a look of horror, and he growled at me, "That's all very fine, doctor, but have you ever tried it?" The retort that I was not a diabetic was obvious and prompt. It was, nevertheless, humiliating to have to confess the negative, and the unpleasant experience determined me never again to be obliged to make a similar reply to what might seem to a layman a perfectly legitimate question. For the next week-end, therefore, I ordained for myself a fast on Allen lines; that is, no food of any kind and only water to drink. Realising the probability and also the inadvisability of hoarding my fæces for the prescribed three days, I took a grain of grey powder on the Friday night and a dose of Epsom salts on the following morning. Then I fasted, secundem artem, until Tuesday morning. On Saturday I felt well, but I am told that my conversation was terse in matter and staccato in manner. On Sunday I felt very well, and endured my trial in the spirit of a Christian martyr. I was resigned. On Monday I felt very well indeed, and did my work at home and at the hospital with zest and vigour. I had arrived at the stage of the superior person who regards meals as mundane matters suitable only to the Philistine and the pork butcher. And truth to tell, I swallowed the cup of tea and the banana which broke my fast on the Tuesday with a certain indefinable regret, as though I had fallen from grace and was no longer worthy to be numbered among the elect.

Since that time, now many years ago, I have frequently repeated the experience, and always with the same result. The first day, craving; the second, resignation; the third, rejoicing and rejuvenescence. The result is that I can cordially recommend the discipline as an occasional exercise to anyone who is obliged to lead a sedentary life. The rationale of its beneficence is probably as follows. In the ordinary routine of town life we do not completely oxidise our intake; there remains a residue which is only partially oxidised. These "suboxides," if I may so term them, are mildly but cumulatively toxic, and give rise to many of the minor maladies and discomforts of everyday life. In the process of fasting these suboxides, which are relatively insoluble, become thoroughly oxidised, and thus fitted for normal and easy excretion.

It is almost certain that the energy which is set apart for our digestive processes takes the path of least resistance. It seizes upon the easily oxidisable, and when that has been disposed of, but not before, it attacks the tougher portion of the proposition. Thus it comes about that the tired horse has the heavier load to pull. Is it any wonder that he falters by the way? The faltering in this case means suboxidation, which can only be corrected by giving an opportunity for an oxidation which is full and free. This is well and physiologically effected by fasting—and by no other means. Sir Henry Lunn says that he sometimes takes cocoa on his days of fast. He will, I am sure, forgive me for saying that, for the reasons given above, he is wrong. Cocoa is more readily oxidisable than, say, urates of soda, and the metabolic energy will naturally seize upon it rather than upon them. The result is a retardation of the curative process. If, instead of a cup of cocoa, Sir Henry Lunn will take half a grain of thyroid, he will expedite his cures and qualify himself to better his present most excellent and timely instruction.

I am, Sir, yours faithfully,
LEONARD WILLIAMS.

Harley-street, W., Dec. 4th, 1921.

THE QUESTION OF SELF-DISINFECTION.

To the Editor of THE LANCET.

SIR,—I have read the letter on this topic in your issue of Dec. 3rd with unusual interest, since I have never been quite able to understand why prophylactic measures against venereal disease amongst Canadian troops met with failure, complete and ignominious, whilst identical measures appear elsewhere to have attained considerable success, notably in the Portsmouth area. That "prevention is better than cure" is customarily regarded as axiomatic; and the Canadian military authorities in England attempted with characteristic vigour and thoroughness, through the medium of instructive lectures and the supply to soldiers proceeding on leave of packets and full instructions as to their use, to reduce the incidence of venereal disease. London, being comparatively accessible to troops in Canadian camps, a special treatment centre, suitably disguised, was established here in charge of a competent genito-urinary specialist, and soldiers urged to report immediately after exposure. As no upsetting questions were asked, no record kept of names and numbers, and they were greeted with neither head-wagging, curtain-lectures, nor sermons, the men made full use of the facilities afforded. After confirmation of the use of the materials which had been supplied, an irrigation with potassium permanganate was given, for which later on was substituted the injection into the anterior urethra of a little argyrol solution, the penis having been first clamped near the peno-scrotal junction and then cleansed with sterile water.

I thought very favourably of the scheme indeed, and as officer i/c treatment at the principal V.D. hospital, an institution with 1300 beds and a large out-patient attendance, I followed with great interest the results, supplementing the figures obtained in our admission-room by inquiries along similar lines in the various units through their medical officers. We finally concluded that the net results of the effort were nil; indeed, the advantage at times seemed with the men who had not availed themselves of the facilities; such are the vagaries of statistics, however painstakingly prepared. Our own hospital personnel, numbering 125, and many of them university undergraduates, were under no illusion as to the value of our prophylactic measures, and customarily declined with thanks both the packets and the treatment, preferring to rely on their own individual methods, usually prompt ablution with soap, and urination.

I hold no brief for either of the Venereal Councils competing for a place in the sun, and the literary weapon discharged by the N.C.C.V.D. will, no doubt, draw a return salvo from the N.C.P.V.D. It may be said, however, that the former base their whole campaign on two fundamental conceptions (or misconceptions): firstly, that the public, and especially the young, are ignorant and must be instructed; secondly, that if the possibilities of venereal disease are vividly brought to their notice they will remain on behalf of the Crown to the effect that where it is alleged that an object has been attempted, or carried out, by two different methods, evidence as to both can be given at the same trial. Dr. Starkie's method, he said, was apparently to administer pills first, and, if they failed, to use instruments. The appeal failed, the court holding that the cases relating to drugs and to the use of instruments could be tried at the same time, and that the jury had been properly directed.

Brown v. *Craig and Pitcairn.*

Mr. J. Gore Brown, whose action against Sir Maurice Craig and Dr. J. J. Pitcairn was tried in May of this year, appealed unsuccessfully for a new trial or for judgment. Mr. J. Gore Brown claimed damages against the two defendants, alleging conspiracy, false imprisonment, and that they had wrongfully certified him as insane. The appeal was dismissed by Lords Justices Bankes, Scrutton, and Atkin, who held that the jury had been properly directed by Mr. Justice Baillhache, and that the only issue raised at the trial was that of a criminal conspiracy by the defendants against the plaintiff. That was the case which the latter had to establish, and his doing so depended chiefly upon the letter alleged by him to have been written by Sir Maurice Craig and denied by the latter. It was argued on behalf of Mr. Brown that there were other matters to which the jury's attention should have been drawn by the judge, but in the opinion of Lord Justice Bankes, who delivered judgment at length, the summing up was fair, sufficient, and satisfactory.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

Edinburgh University Chair of Midwifery.

THE University Court of Edinburgh has decided that the teaching of gynæcology is to be combined with the duties of the chair of midwifery. The salary under the new arrangement will be £1200, the professor being allowed to undertake private practice. The curators are to consider on Dec. 16th the names of those qualified for the appointment.

Scottish Voluntary Hospitals.

A report compiled by Sir Napier Burnett shows that there are 94 voluntary hospitals in Scotland with 6981 available beds. Eighteen hospitals have each over 100 beds and account for 4913 beds. Five hospitals, with a total of 2933 beds, are attached to medical schools. The report itself deals with 78 hospitals with 6600 available beds. These hospitals treated during 1920 92,000 in-patients and 310,000 out-patients. The hospitals attached to the medical schools treated altogether nearly 200,000 patients, or approximately 48 per cent. of the total. During the year hospital expenditure was very high, but there is every indication that the present year will show considerable reduction of the cost of many hospital commodities. Good results are anticipated from the committees now being established by the Voluntary Hospitals Commission as regards coördinating and financing hospitals within near distances of each other, and in organising coöperative buying. It is also considered that the adoption of a simplified system of hospital accounts and a uniform financial year would result in considerable benefit.

The demand for beds was greatest in the large hospitals. In those with over 100 beds approximately 92 per cent. were occupied during the year; in intermediate hospitals, with 30 to 99 beds, the figure was 81 per cent., and in hospitals of less than 30 beds 77 per cent. Comparing the non-teaching hospitals with over 100 beds in England and Scotland, there was little difference in the ordinary expenditure per available bed: but in the teaching hospitals there was a remarkable difference: the English group show deficit of £55 as against £15 per available bed in the case of the Scottish group. Workmen's contributions form a much smaller proportion of hospital income in Scotland than in England. Local Hospital Saturday collections form a rich source of revenue if properly organised, and this method of obtaining funds appealed to an increasingly large number of hospitals during the year. There is a prospect of larger contributions being received in future from the approved societies under the Insurance Acts.

Orphan Homes of Scotland.

Sir Joseph Maclay presided at the annual meeting held at Glasgow of subscribers to the Orphan Homes, the Consumptive Sanatorium, and the Colony for Epileptics at Bridge of Weir. The report contained the record of the fiftieth year's work of the Orphan Homes of Scotland. During the last year the average number of children in the homes was about 1100. During the war many children of soldiers were cared for, but most have been returned to their fathers during the past year. Fifty-one boys had gone to Canada, a country where they had the best chance of making good, and which numbered amongst useful citizens many who had gone from these homes. Fifty-one children had gone to various trades and situations. The healthiness of the homes was remarkable, there having been only four deaths out of the average of 1100 children. In the Consumptive Sanatorium the average number was 152 patients, of whom approximately 50 per cent. were discharged fit to resume ordinary life. In the Colony for Epileptics there were 103 patients.

The Royal Infirmary, Edinburgh.

The third annual meeting of the League of Subscribers to the Edinburgh Royal Infirmary was held on Nov. 29th, when Mr. Paton, the organising secretary, reported that the results attending the organised collections on behalf of the infirmary from public works and business establishments had shown a steady progress, a total of £17,808 having been collected from the various groups of subscribers. The bulk of employees' contributions from the country districts, including those raised by the miners and oil-workers, were reckoned separately from the League funds, and the total raised from these sources would this year be not less than £15,000. In round figures the systematic contributions of organised labour yielded something like £32,000 to the infirmary, which was equal to about one-quarter of the cost of maintenance. The present membership of the League consisted of 989 groups, composed of from thousands to less than a dozen members in different districts. Sheriff Crole, chairman of the board of management, gave some interesting figures concerning the work of the institution. The in-patients for the year numbered 13,600, drawn almost equally from the city and the country, while the out-patients numbered 41,800.

Fourteen years ago the income of the institution was £50,000; now it was over £130,000, but it required great efforts to keep it up to that. The current accounts had not yet been audited, but the income from all sources would show a balance to the good over expenditure. The year's accounts were another triumph for the voluntary system. The total contributions for the year from approved societies amounted to £1709, a disappointing figure, seeing that there were some 200 societies, and nearly 29,000 members had received benefit; yet only 15 societies had given anything out of their surplus to the infirmary. Within the years 1913–18 they had received into the wards 29,000 insured persons, and had treated as out-patients 49,215, and the infirmary had expended upon these in-patients alone over £148,000.

Sheriff Crole recounted work at present being carried out in the infirmary involving capital expenditure. The whole of the heating system was being remodelled at a cost of £15,000. The departments that were being developed were those for X rays and radium, and the bio-chemical laboratory; larger conscious creatures . . . . experiments of a light-bearing kind, you may rightly undertake in the unreflecting animal in the hope of cure which in man cannot be tried without very long periods of tentative proofs . . . . but the large view of the matter is that disease pertains to the whole field of life, animal and plant, and that without the comparative method no science has flourished."

Clearly, then, the obvious course seems to be that human and comparative pathological research should be more closely linked together in the future than they have hitherto been in the past.

I am, Sir, yours faithfully,
W. M. SCOTT, F.R.C.V.S.

Bridgwater, Dec. 3rd, 1921.

BLOOD-DONORS.

To the Editor of THE LANCET.

SIR,—The annotation in your issue of Nov. 26th on the question of blood-donors may tend to bring the subject into that prominence which is at present lacking in this country. I am in cordial agreement with the writers in the *Guy's Hospital Gazette* and *St. Bartholomew's Hospital Journal* and would deprecate the use of the medical student's blood for purposes of transfusion. Up to the present one has usually depended on some relative of the patient to provide the necessary blood in an emergency, but occasions must arise when such will not be available. Last year, in order to meet this difficulty, I examined and classified the blood of a large number of the Sheffield constables, thinking that they were a healthy body of men and easily procurable in a sudden emergency, but unfortunately, after the classification was completed, the Sheffield Watch Committee refused to allow me to utilise the blood of volunteers from their men. I have recently applied to the manager of the tramways for similar facilities, expecting a like answer, as there are obvious objections to the use of men on public duty. I think it would be of advantage if donors could be selected from the general population by some carefully worded advertisement asking for volunteers, each volunteer to receive a small fee for submitting to grouping tests, and, in the event of his blood being used, a fee of at least five guineas.—I am, Sir, yours faithfully,

Sheffield, Dec. 1st, 1921. E. F. SKINNER.

OCCUPATIONAL THERAPY IN HEART DISEASE.

To the Editor of THE LANCET.

SIR,—I was much interested in your annotation on physical exercises in the treatment of heart disease in the issue of Nov. 5th; also in the letter of Dr. I. Harris on the 26th, both referring to my communication of Oct. 22nd. In neither comment, however, was the essential part of my letter discussed, the remarks being confined to the general question of the value of exercises in the treatment of heart disease. The point I desired to emphasise was the humanitarian and economic importance of looking upon the beneficial effects of physical exercises, not as an end in itself, but as means for the acquisition of a capacity for work in a line compatible with the patient's physical powers, always keeping in view his adaptability to a change of occupation. To achieve this, patients should be carefully graded and training begun at an early period of convalescence; such training should be specially directed towards preparation for the kind of work appropriate to each case subject to modification where necessary. I have pointed out the unsatisfactory results which follow the return of a patient convalescent from an attack of heart failure to an occupation which had abundantly manifested its unsuitability. In this connexion a quotation from a pamphlet, entitled "Sanatoria for Cardiacs," issued by the Association for the Prevention and Relief of Heart Disease, N.Y.:—

"The value of sanatorium treatment of convalescent cardiacs has passed the experimental stage. Experiences with selected groups of children and young adults have shown the tremendous value of institutional treatment in securing a degree of recovery which affords them the opportunity for useful lives and self support. The results obtained by the Burke Foundation, which has cared for over 2000 selected cases in the past six years, are most convincing. Of 130 boys between 10 and 16 years of age received during the first two years and carefully followed, 85 per cent. have remained steadily at work or at school since leaving the institution. The results obtained in adults and more advanced conditions are less striking, but the economic advantage of rendering a large proportion of these sufferers self-supporting and no longer a financial burden to the community, as well as the humanitarian motive of prolonging life and assuaging suffering, should make an urgent appeal to both our pockets and our sympathies."

In another pamphlet from the same source on *Occupation for Cardiacs* occur remarks under the following headings: Danger from Overstrain, Choosing a Job, General Housework, Skilled Employments, Employer's Coöperation, Change of Occupation. With regard to the latter, the important point in making a selection is that the new job should demand as little physical exertion as possible. The writer of this pamphlet concludes: "There are but few cardiacs who cannot do something to earn a living, and many of them can earn as good wages as if they had no disease whatever."

That the subject of heart disease, its prevention and treatment—including occupational therapy—is being systematically studied in America medical literature bears ample proof. The question is, Are we in this country doing our share in the practical application of the knowledge we possess?

I am, Sir, yours faithfully,
CHARLES W. CHAPMAN.

Harley-street, W., Nov. 30th, 1921.

THE SUSSEX PROVIDENT SCHEME: FIRST YEAR'S WORKING.

To the Editor of THE LANCET.

SIR,—In view of the fact that some doubts have been expressed as to the economic soundness and financial stability of the Sussex Provident Scheme, it may interest some of your readers to hear the results of the first 11 months' working. It was decided to make the first financial year one of 11 months in order that the associated hospitals might receive what was owing to them before the last quarter day of the current year. The financial arrangement which was agreed to when the scheme was initiated was that, for the first year, the income of the scheme should be divided into 40 parts and that these should be allotted beforehand to the associated hospitals, in a varying proportion based upon the work which each might be expected to do. This was, of course, a purely experimental arrangement and subject to being changed in the light of the first year's experience, but the results which have been attained will be of value in the future whether the scheme maintains its existence or not.

One satisfactory result is that, although some hospitals have been favoured more than others, they have all been paid in full for the cost of the services which they have rendered to the members of the scheme during the year; but beyond this 100 per cent., the percentage of payment to the cost of the work done varies very considerably. One hospital which, so far as can be ascertained, has not been called upon for any service to the members of the scheme has been paid one-twentieth of the total income, and of the others the percentage varies from 105 at the Brighton, Hove, and Preston Dispensary, to 307 at the Sussex Throat and Ear Hospital. At the New Sussex Hospital for Women and Children and the Stephen Ralli Memorial Laboratory it reaches 108, while at the Royal Sussex County Hospital it amounts to 117·5. The Dental Hospital has been paid at the rate of 15*s.* 4*d.* a visit. The visiting consultants have been paid a fee of £3 3*s.* for each consultation, while one-eighth of the total income still remains in

Correspondence.

"Audi alteram partem."

GENERALIA ON THE LOUSE PROBLEM ON THE WESTERN FRONT.

To the Editor of THE LANCET.

SIR,—Mr. A. D. Peacock's letter appearing in your issue of Nov. 19th in reply to mine which appeared on April 30th hardly disposes of the subject of combating lousiness amongst troops in the field. There is a plain issue between us as to the proved utility of certain types of disinfestor as well as the question of responsibility, and I therefore trust that I may be allowed to state my experience as a sanitary officer for the benefit of others likely at some time or other to be as acutely interested. I have already said that no type of hot-air disinfestor was ever used in the Second Army during the period of my appointment as Sanitary Officer. This circumstance was due entirely to the unreservedly adverse report furnished in the winter of 1916–17 by Mr. Peacock, who, after considerable experimental investigation in the field of certain proposals first communicated to me by Mr. Bacot, entomologist of the Lister Institute, stated that hot-air disinfestation was not only useless but dangerous. I have already cited his reasons in detail. Mr. Peacock now states: "I admit my judgment of 1916–17 was somewhat premature on certain points, but the seriously impairing effect of wet and muddy garments upon hot-air disinfestors still remains a fact (sic)." I want to make it quite plain that during the whole period of my service in forward areas in France, Italy, and North Russia (some five years) I have never once seen a hot-air type of disinfestor in use.

Mr. Peacock's duty in the Second Army was to report, as entomologist, upon the efficiency of various types of disinfestor in use, as well as upon the value of insecticides. The two main methods of disinfestation were steam and the Clayton apparatus (i.e., fumigation by SO_2 and SO_3). Again and again I was assured by Mr. Peacock that he had no fault to find with either of these systems, and therefore his present attitude with regard to the Clayton apparatus is beyond my understanding. I would like to add that in North Russia, on the Murmansk front, where the troops came into close contact with cases of typhus and small-pox amongst the civilian population, we were entirely without disinfesting or disinfecting apparatus of any description. I therefore turned my attention to utilising for this purpose the large chamber of a discarded railway box-wagon to be used as a mobile disinfestation and disinfection chamber in which were hung garments and equipment to be treated. The fumigating gas was obtained by burning sulphur prepared in a special manner to facilitate combustion. The special preparation consisted of sheets of newspaper, cut approximately foolscap size, which had been coated on both sides with a thin layer of sulphur. This was done by momentarily dipping the sheets into a vessel of molten sulphur and hanging them in the air until the film of sulphur had cooled and solidified—a rapid procedure. A number of such prepared sheets was loosely bound together with a few strands of wire to form "brimstone books," which were suspended in mid-air by a wire attached to suitably placed hooks in the roof of the wagon. On the floor, immediately underneath each suspended "book," was placed a tray filled with sand in order to catch such drops of burning brimstone as might be set free and fall. The wagon having been made gas-tight and suitably charged with the material to undergo treatment, a sufficient number of "brimstone books" was suspended and set alight by the operator, who thereupon withdrew and closed all doors, the compartment remaining closed for a period of three to five hours. A similar method of disinfestation was employed for all civilian houses requiring treatment, and in no case did an accident by fire occur nor did a single case of typhus or small-pox arise amongst our troops. The only billets available were the civilian houses, nearly all of which were built of rough logs resting simply on one another, the intervening space being roughly plugged with felt, which formed a natural harbour for lice, bugs, and other "minor horrors." On the principle that "handsome is as handsome does," I think that burning brimstone should be given pride of place in the armamentarium of a sanitary officer, for it was our only help in a critical and lonely situation, and in this connexion I regretted the absence of the Clayton apparatus, which had proved during long years so reliable and dependable in the field in France and Italy and on other fronts as the easiest and readiest means for producing, controlling, and distributing the gases of burning sulphur. If Mr. Peacock "personally wrestled wholeheartedly with the plant on many a day" he shows that he did not know how to handle it, and he therefore failed to get the good results obtained by hundreds of men who handled it properly. I have not seen the manuscript report Mr. Peacock made to the War Office, but surely he did not base his condemnation on the score of expense or the mechanical difficulty he experienced in working the machine; or does he condemn the machine because he now considers the gas is an inefficient insecticide?

With regard to the general question of responsibility for the anti-louse measures taken, Mr. Peacock may be interested to learn that the so-called "louse problem" was recognised even in the early days of the war at the base camps. The first recorded attempt to deal with the matter was made by No. 1 Sanitary Section of the Regular Forces at No. 1 Base at St. Nazaire. By October, 1914—fully a year before Mr. Peacock's attention had been drawn to the matter—an organised scheme of disinfesting and bathing of troops was at work. Use was made of the steam disinfector at the "Service Sanitaire Maritime," augmented by improvised apparatus constructed out of packing cases, oil-drums, and copper tubing. Hot baths were obtained by the use of waterproof sheets, "lessiveuses," and tubs procured locally. Some 80 to 100 men and their belongings were dealt with daily, and local requirements were adequately met. It is important to note in this connexion that the men under treatment had arrived from England but a few days previously, and it was already proved at that early stage of the war that the fresh arrivals in France were responsible for the infestation of the camps. Not only was the "louse problem" among troops in camps realised and overcome, but all improvised ambulance trains, contents included, arriving at the base were dealt with by disinfecting squads, as a routine measure, immediately after unloading. The possibility of an outbreak of typhus amongst troops in the forward area was considered both in December, 1914, and January, 1915, when Major-General Sir Robert Porter (Director of Medical Services, Second Army) asked me to prepare a scheme for dealing with disinfestation of troops on a large scale should necessity arise. In the end, arrangements were made to earmark in the neighbourhood of Steenwoorde some 30 agricultural locomotives of a stationary type to be used as steam disinfestors, and, in addition, all hop-oasts (i.e., drying kilns) between Bailleul and Poperinghe, and all chicory kilns in the neighbourhood of Dickebusch, Reninghelst, and Vlamertinghe were similarly ear-marked to be utilised as fumigation chambers.

Lastly, with reference to the method employed officially for ascertaining the extent of lousiness amongst troops (namely, by direct inquiry from officers in medical charge of troops and from officers in charge of medical units receiving sick and wounded men) Mr. Peacock affirms that he can conceive of no method better than his own—"i.e., by doing the job personally and thoroughly from the front line backwards: *living it, not reading it*" (the italics are my own). I would remind him that, although he necessarily had no knowledge of plans and no first-hand knowledge of operations, it was beyond the capacity of any individual his advocacy of the practice of cremation chiefly to persuasive conversations with his personal friends. he was keenly interested in the adoption of this as a hygienic method of disposal of the dead. He was the author of many well-written papers on widely different subjects, ranging from reflections on The Antiquity of the Globe and on The Principles of Organology to contributions to the therapeutics of variola, chronic gastric catarrh, and typhoid fever. A man of wide general culture, his experience of continental as well as British methods of diagnosis and treatment of disease gave him a well-deserved reputation as a wise physician.

WILLIAM GORDON WOODROW SANDERS,

M.D. MONTPELLIER, F.R.C.P. EDIN.

THE death of Dr. Gordon Sanders in early middle life has removed one of the best known British practitioners on the French Riviera. Dr. Sanders came of a medical family. His grandfather practised in Edinburgh; his father was professor of pathology in the University. He graduated there himself in 1889, with first-class honours, becoming clinical tutor in the medical wards of the Royal Infirmary. After a brief attempt to carry on the family tradition in the city of his upbringing he was obliged by ill-health to go abroad. A few months' residence at the University of Montpellier procured for him the doctorate, and therewith the right to practise on French soil, and he spent the remainder of his life at the delightful and important climatic station which Lord Brougham made famous in the early 'forties. With native ability and zeal for work, combined with an intuitive instinct as a clinician, Dr. Sanders made a large circle of friends among the patients who return to Cannes year after year to avoid the Northern winter.

While still at Edinburgh Dr. Sanders presided for some years over the Medical Society, and his personal interest in cardiac pathology resulted in a series of papers dealing with malformations of the heart and cardio-pulmonary murmurs. Since 1894 he had been a Fellow of the Royal College of Physicians of Edinburgh. Abroad he was an active member of the Continental Anglo-American Medical Society.

THE LATE PROF. PETER THOMPSON.

LAST week we gave a brief record of Prof. Thompson's life-work, largely from the administrative standpoint. His fellow anatomist, Prof. James C. Brash of Birmingham, writes of him from two other points of view.

"Prof. Thompson was great as a teacher and great as an investigator. Into his teaching work he poured the energetic enthusiasm which was a leading feature of his character, and dull must he have been who could not respond to such a stimulus. He was at his best in his devotion to the exposition of what he always thought and spoke of as the wondrous tale of development, and in this connexion it has been said of Prof. Thompson (a new version of the stock phrase, in praise of the anatomical lecturer. about making the 'dry bones live') that he made for his students out of a difficult subject a fascinating fairy-tale.

"His original work falls naturally into two periods, separated from each other by the date of his appointment to the King's College chair. The first of these periods was morphological, the second embryological, and in both he did outstanding work. His work on the muscles of the pelvis is well known, and apart from its comparative value has passed into standard description. 'The Myology of the Pelvic Floor,' presented as an M.D. thesis, was a model of descriptive writing, expanded later in a series of papers, and finally summed up in an article on 'The Structures of the Pelvic Outlet' in the fourth edition of Morris's Treatise on Anatomy. The turning-point of his career as an investigator came in the summer of 1906 when, working under Profs. Wiedersheim and Keibel at Freiburg, he became practically acquainted with modern methods of embryological work. His work on a human embryo 2·5 mm. long from the collection of Dr. Robert Meyer in Berlin resulted in the well-known paper in the *Journal of Anatomy and Physiology* in 1907, 'Description of a Human Embryo of Twenty-three Paired Somites,' beautifully illustrated by drawings provided by his wife. He had constructed a model of the embryo. This was his introduction to the wax-plate method of which he became an enthusiastic exponent, and to his advocacy of which may be traced a good deal of subsequent work in this country.

"It remains to note some special features of Prof. Thompson's work during his Birmingham period. Soon after his appointment he delivered two special post-graduate lectures on 'Some Early Human Embryos' to large and appreciative audiences. In 1910 his Arris and Gale lectures on 'Some Embryological Problems in Relation to Medicine,' published in THE LANCET, dealt with many points of practical interest in the development of the thyroid, the lung buds, the liver, and the heart. In 1915 he enhanced the reputation of his department by bringing to fruition an illustrated volume, published by the University Council, of 'Studies in Anatomy,' his own contribution being a valuable study of a 7 mm. human embryo."

Prof. Brash gives many further evidences of his colleague's devotion to his task. Up to the time of his death Thompson continued to work, as his health allowed him, at a paper describing an early human ovum mentioned in his Ingleby Lectures of 1918. Such in brief outline, Prof. Brash adds, was the career of one who, stricken in his prime, had yet accomplished much, and whose loss is a hard blow to his friends and to the University which he adorned.

Medical News.

UNIVERSITY OF OXFORD.—The following degree has been conferred:—

M.D.—W. H. Butcher, St. John's.

UNIVERSITY OF CAMBRIDGE.—The following degrees have been conferred:—

M.D.—C. J. Stocker, Trinity.

M.B. and B.Ch.—F. P. N. Parsons, Pembroke; R. S. Scott, Caius; G. W. Theobald, Emmanuel.

M.B.—J. M. Higgington, St. John's; R. B. P. Lansdown, Pembroke: G. P. N. Richardson, Christ's.

SOCIETY OF APOTHECARIES OF LONDON.—At examinations held recently the following candidates passed in the subjects indicated:—

Surgery.—H. Amin, Guy's Hosp.; J. L. Delicati, Bristol; E. D. Foster and J. S. Lewis, St. Mary's Hosp: and J. A. Marriott, Manchester.

Medicine.—A. G. L. Brown, Westminster Hosp.; S. Cohney, Sydney and London Hosp.; W. E. F. Davidson, St. George's Hosp.; M. T. A. Elnakeeb, Cairo; R. Erskine-Gray, Charing Cross Hosp.; E. D. Foster, St. Mary's Hosp.; S. A. Hayes, Kingston, Ontario; R. Henein, Manchester; M. Hilmy Eid, Cairo and Guy's Hosp.; C. F. Long, Bristol; D. Menzies and A. Misbriky, St. Mary's Hosp.; S. Sedaros, Cairo and Guy's Hosp.; L. Spira, Vienna; and R. S. Thomas, Charing Cross Hosp.

Forensic Medicine.—A. G. L. Brown, Westminster Hosp.; M. T. A. Elnakeeb, Cairo; E. D. Foster, St. Mary's Hosp.; R. Henein, Manchester; C. F. Long, Bristol; C. Martiny, Copenhagen; L. Spira, Vienna; and H. M. White, Leeds.

Midwifery.—J. I. Cahill, Middlesex Hosp.; A. G. L. Davidson, St. George's Hosp.; M. T. A. Elnakeeb, Cairo; E. D. Foster and A. Misbriky, St. Mary's Hosp.; and C. A. Nicholl, London Hosp.

The Diploma of the Society was granted to the following candidates entitling them to practise medicine, surgery, and midwifery: W. E. F. Davidson, J. L. Delicati, E. D. Foster, R. Henein, M. Hilmy Eid, C. F. Long, and D. Menzies.

HISTORY OF MEDICINE: THIRD INTERNATIONAL CONGRESS.—This congress will be held in London, under the presidency of Sir Norman Moore, from July 17th to 22nd, 1922. Meetings will be held at the Royal Society of Medicine, the Royal College of Physicians, the Royal College of Surgeons; also at the Wellcome Historical Museum, where there will be an exhibition of objects connected with the history of medicine, surgery and the allied sciences, including ancient manuscripts, early printed books, pictures, sculptures and engravings, ancient surgical instruments, medals, and so forth. The subjects suggested for discussion by the International Society of the History of Medicine are: (1) The principal seats of epidemic and endemic disease in the Middle Ages, including plague, gangrenous ergotism, leprosy, and malaria; (2) the history of anatomy. Further information may be obtained from the general secretary, Dr. J. D. Rolleston, 21, Alexandra Mansions, King's-road, London, S.W. 3.

chaste. Some acquaintance with the psychology of youth, particularly in relation to sex matters, leads me to think that both these propositions are untrue. I am tempted to ask the N.C.C.V.D. the following pertinent questions:—

1. Are they quite satisfied that the statistics upon which they base their activities are accurate?

2. Is it not true that the number of "cases" automatically increases as the number of treatment centres is increased; the patients often visiting many centres in turn, so that "one" becomes in completed statistics "six," "ten," or more? We know that with dissatisfied patients this occurs.

3. Do they know that with venereal disease there is often associated a peculiarly characteristic mental depression and a tendency to introspection, due, perhaps, in the first instance to the exaggerated warnings of quacks, but also in some measure attributable to the deductions of the type of scientist who reasons from one to all?

4. Do they admit any connexion between their graphic descriptions of the "horrors" of venereal disease and the present increase in sexual hypochondriasis?

5. Do they not consider that the perusal of certain of their pamphlets may cause unnecessary suffering and anxiety to those unfortunately already infected? Or doesn't it matter?

6. Are they psychologically sound in regarding deviation from virtue as resulting from a calmly considered and rational decision? On the contrary, is it not usually an unreasoning act, the result of an emotional storm?

7. Do they believe their extensive, and expensive, campaign to be justified either by social conditions or, more important, any actual improvement attained?

8. Do they visualise the extent of the disservice their publications are doing and have done to this country abroad, and particularly in the United States?

9. Has the campaign greatly benefited anyone, excluding possibly the manufacturers of expensive "ethical" venereal remedies?

I am, Sir, yours faithfully,
HAROLD D. L. SPENCE, M.D.

Catoline-street, Bedford-square, W.C., Dec. 2nd, 1921.

THE ÆTIOLOGY OF ADENOIDS.

To the Editor of THE LANCET.

SIR,—I do not contend that the food factor is the only factor in the causation of adenoids. All causation is complex, and it is only for practical purposes that we single out one particular factor and speak of it as the cause. If the data I have enumerated in my letter in your issue of Nov. 19th are accurate, it follows as a logical conclusion that the great preponderance of adenoids among British children is related to the peculiar nature of the British diet. The only way Mr. W. Rushton (Dec. 3rd) can cast legitimate doubt on that conclusion is by disproving the accuracy of the data, and this does not seem to me possible. The citation of two or three special cases as proof that I am exaggerating the food factor in the ætiology of adenoids carries little weight. What is needed is to compare, as I have done, the relative frequency of this disease among large numbers of children brought up on British diet with large numbers of children brought up on a non-British diet.

But even the cases cited by Mr. Rushton are not convincing. They do not answer to my conception of properly fed children. The first child was breast-fed for six months only and developed rickets. The other two children were bottle-fed from birth. The fact that all three developed adenoids and tonsils suggests a pronounced catarrhal diathesis in each case, and this again suggests defective intestinal digestion, of which the most common cause in children is improper food. Dr. Sim Wallace, Mr. Rushton tells us, "attributes adenoids to weather conditions." While Dr. Wallace and I are in agreement on many questions, on this point I am reluctantly compelled to differ from him. There is no room for compromise in regard to it. In so far as damp predisposes to catarrh (a bacterially induced inflammation) it may help to produce adenoids; but the average child, if properly fed and enjoying in consequence a sound intestinal digestion, has little tendency to suffer from those catarrhal infections which issue in adenoids. The climate of our country has been damp for thousands of years, but we have the evidence derived from disinterred skulls that it is only within comparatively recent years that adenoid disease has been common in this country. Consider also the fact that, although (strange to say) rickets is almost unknown in Australia among the white children, adenoids is rampant among them. I may add that this disease appears to be equally common among the white children in South Africa. One of the worst cases I have ever seen occurred in a British child who was brought up on the veldt!

Can Mr. Rushton escape from the conclusion to which these facts point?

I am, Sir, yours faithfully,
HARRY CAMPBELL.

Wimpole-street, W., Dec. 3rd, 1921.

PATHOLOGICAL RESEARCH: HUMAN AND COMPARATIVE.

To the Editor of THE LANCET.

SIR,—The science of pathology has made enormous advances during the last two decades, but great indeed as these are, where is the man who will deny that the more he studies and the more he learns, the less he seems to know, ever and anon emphasising the great home truths that a vast realm of unexplored territory awaits the enthusiast for investigation. Even in the field of routine cases which we see in practice daily, where clinical data appear to present themselves in almost standardised sequence, often leave us nonplussed when we take the trouble to verify our conclusions by an autopsy. This is an unsatisfactory state of affairs. In human medicine post-mortem verifications, largely for sentimental reasons, are tabooed, much valuable material being thereby lost to science. Such a plea, however, cannot be put forward by the practitioner of comparative medicine, for here sentiment counts less; nevertheless, the busy veterinary practitioner invariably loses active interest in his case the moment death steps in, simply because he cannot afford the time to make a special visit to the knacker's. What an enormous volume of valuable script is committed thus yearly to oblivion only those who come directly in touch with the subject-matter can realise. Has the time, therefore, not arrived when some scheme could be instituted whereby data and material might be collected at the animal "morgues" distributed throughout the country?—the veterinary surgeon attending selected cases supplying clinical history, &c. Knowledge as to the cause and course of disease in its most diverse form would be tapped to the economic benefit of the human and animal population. By such a scheme at first sight it may be urged comparative pathology would gain much and human pathology little, but in reality this would not be so, for the connecting link between animals and man, from a medical point of view, is very close indeed.

One need only cite experimental research work performed in animals to illustrate the benefit which man derives from comparative pathology. Further, a larger and broader outlook on the field of medicine is required from all of us to-day, and bearing on this point Sir Clifford Allbutt writes:—

"The address you enclose to me contains on every page illustrations of the cross lights which each branch of morbid biology would throw upon the rest. Many little points which to you seem of every-day interest are new to me in this sense, that they illuminate principles which in human medicine are less prominent, in your field they shine out with a new perspective. For instance, you can with every kindliness and caution act at your own discretion unhampered by hesitations coming of the fear and reflections of more

ROYAL NORTHERN HOSPITAL. — The Great Northern Central Hospital, Holloway, will henceforth be known as the Royal Northern Hospital.

SANATORIUM BENEFIT IN MANCHESTER. — An elaborate report has been issued by the Sanatorium Benefit Sub-Committee of the Manchester Insurance Committee dealing with the period from July, 1912, to the end of April, 1921, when the work was passed over to the Manchester Corporation. Three hundred beds were secured in sanatoriums and other institutions, and a special tuberculosis dispensary service was set up in the city capable of dealing with 1248 persons weekly. During the period included in the report, 8139 applications were received from insured persons eligible for sanatorium treatment—5690 from men and 2449 from women. A table of age-groups shows that between the ages of 16 and 50 the number of applications from men remained fairly constant; the greatest number from women was between the ages of 16 and 21, most probably because many women ceased to insure on becoming married. Statistics show that the cases from the several wards of the city were most numerous from the poorer and more congested areas—the percentage varying from 0·45 to 2·06—the average percentage over the whole city being 1·14. Of 5690 men treated, 770 showed no signs of active tuberculosis, and of 2449 women, 445 gave similar records. Emphasis is laid on the importance of early notification of the disease; applications for sanatorium benefit have in the past been received from persons who died a few days afterwards. A considerable number of patients left the various institutions before the termination of their period of treatment or declined an extension of this period, and most of these self-discharges seemed to be due to domestic circumstances; for the same reason some patients found it impossible to enter an institution for treatment. The committee express the view that "their work has largely contributed to the progress made in Manchester in the treatment of this disease." Dr. D. P. Sutherland, senior tuberculosis officer of the committee, adds that during the period of sanatorium benefit the death-rate from pulmonary tuberculosis fell from 1·53 to 1·10, and associated with this fall there was an increased survival rate of infected notified cases. Of undoubted sputum-positive cases of tuberculosis during 1913-17, 67 per cent. were known to be living at the end of 1919. For sputum-negative cases for the same period the figure was 82 per cent.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MEETINGS OF SECTIONS.

Monday, Dec. 12th.

WAR: at 5.30 P.M.
Paper:
Colonel H. W. Grattan: Medical Organisation, with Special Reference to the Transport of Wounded in Open Warfare.

Tuesday, Dec. 13th.

THERAPEUTICS AND PHARMACOLOGY: at 4.30 P.M.
Paper:
Dr. H. W. Vines: The Parathyroid Gland in Relation to Calcium Metabolism.

Wednesday, Dec. 14th.

PSYCHIATRY: at 5.30 P.M.
Paper:
Dr. T. A. Ross: Some Points about Repression.

Thursday, Dec. 15th.

DERMATOLOGY: at 5 P.M. (Cases at 4.30 P.M.)
Cases. The following will be shown by:
Dr. George Pernet: (1) Morphœa Faciei. (2) Parakeratosis *Variegata.*
Other cases will be shown.
Paper:
Major A. E. Milner: Diathermy in the Treatment of Lupus Erythematosus.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.
MONDAY, Dec. 12th.—8.30 P.M., Paper by Dr. Aldo Castellani on *Hæmorrhagic Bronchitis of Non-Tubercular* Origin.—Demonstration by Dr. J. S. Owens on Dust in Expired Air.

THE ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE, 11, Chandos-street, Cavendish-square, W.
THURSDAY, Dec. 15th.—7.15 P.M., Demonstration by Dr. A. Balfour and Dr. D. E. Anderson of Views, Photos, and Other Objects of Interest from Mauritius. 8.15 P.M., *Paper by Dr. A. Balfour*: A Medical and Sanitary Survey of Mauritius—Past, Present, and Future.

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN, 17, Bloomsbury-square, W.C.
WEDNESDAY, Dec. 14th.—8 P.M., Prof. H. G. Greenish and Miss C. E. Pearson: Volatile Oils in Pills (communication from the Society's Research Laboratory). Mr. T. E. Wallis: Moths as Pests in the Pharmacy (Corcyra, Ephestia and Borkhausenia).

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.
MONDAY, Dec. 12th.—5 P.M., Dr. Scott Pinchin: Differential Diagnosis of Pulmonary Tuberculosis (2).
TUESDAY.—5 P.M., Mr. Page: Anæsthesia (2).
WEDNESDAY.—5 P.M., Dr. Grainger Stewart: Facial Palsies.
THURSDAY.—5 P.M., Mr. Bishop Harman: Senile Cataract.
FRIDAY.—5 P.M., Mr. Steadman: The Relation of Dental Sepsis to the Public Health.
Daily:—10 A.M., Visit of Post-graduates to Wards. 2 P.M., In-patient, Out-patient Clinics and *Operations.*

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.
MONDAY, Dec. 12th.—4.30 P.M., Dr. J. Bright Bannister: Puerperal Sepsis.
TUESDAY.—3.30 P.M., Dr. F. G. Crookshank: Physical Examination of the Chest (4)—The Exploring Syringe.
FRIDAY.—3.30 P.M., Dr. T. H. C. Benians: The Laboratory Diagnosis of Tuberculosis in Children.
Daily:—2.30 P.M., In-patient, Out-patient Clinics, Operations, &c.

NATIONAL HOSPITAL FOR DISEASES OF THE HEART POST-GRADUATE COURSE, Westmoreland-street, Marylebone, W.
MONDAY, Dec. 12th.—5.30 P.M., Lecture:—Dr. R. O. Moon: Arterio-Sclerosis.
Daily:—10 A.M. and 2 P.M., Out-patients and In-patients.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.
THURSDAY, Dec. 15th.—4 P.M., Lecture:—Dr. R. Hutchison: The Problem of the Solitary Child.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN, 49, Leicester-square, W.C.
THURSDAY, Dec. 15th.—6 P.M., Chesterfield Lecture: Dr. W. Knowsley Sibley: Acne.

MANCHESTER ROYAL INFIRMARY POST-GRADUATE CLINIC.
TUESDAY, Dec. 13th.—4.30 P.M., Mr. P. R. Wrigley: Enlarged Prostates.

MANCHESTER FRENCH HOSPITAL POST-GRADUATE LECTURES, 24, Acomb-street, Whitworth Park.
THURSDAY, Dec. 15th.—4.30 P.M., *Dr. N. C. Haring*: Fluid in the Chest.

ST. MARY'S HOSPITALS POST-GRADUATE LECTURE, Whitworth-street West Branch, Manchester.
FRIDAY, Dec. 16th.—4.30 P.M., Dr. Ward: Treatment of *Bronchial Affections in Children.*

SALFORD ROYAL HOSPITAL.
THURSDAY, Dec. 15th.—4.30 P.M., Dr. C. C. Heywood: Thoracic Tuberculosis in Children.

UNIVERSITY OF SHEFFIELD—FACULTY OF MEDICINE.
Post-Graduate Lectures and *Demonstrations.*
TUESDAY, Dec. 13th. (At the Royal Infirmary.)—3.30 P.M., Mr. J. Mouat: Complications of Traumatism. 4.15 P.M., Prof. J. B. Leathes: Nephritis.
FRIDAY. (At the Royal Hospital.)—3.30 P.M., Dr. E. F. Skinner: Neurosyphilis. 4.15 P.M., Dr. G. E. Mould: Classification of Mental Diseases.

BRITISH MEDICAL ASSOCIATION (North of England Branch).
FRIDAY, Dec. 16th. (At the Royal Victoria Infirmary, Newcastle-on-Tyne.)—2.15 P.M. to 5 P.M., Scientific Demonstrations.

Vacancies.

For further information refer to the advertisement columns.

All Saints Hospital for Genito-Urinary Diseases, Vauxhall Bridge-road.—Res. H.S. £160.
Ashton-under-Lyne District Infirmary.—H.S. £200.
Barry Accident and Surgical Hospital.—S. £750.
Bath, Royal United Hospital.—H.P. £180.
Birmingham Ear and Throat Hospital.—H.S. £200.
Birmingham, Ministry of Pensions Orthopædic Centre.—Jun. M.O. £350.
Birmingham, Queen's Hospital.—Obst. and Ophth. H.S. Each £90.
Bristol Royal Hospital for Sick Children, &c.—H.P. £150.
Bristol Royal Infirmary.—H.P. and H.S. £120 each. Ophth. Hon. Reg.
Bury Infirmary.—Jun. H.S. £150.
Cape Town University.—Sen. Lecturer in Physics. £450.
Cheadle, Barnes Convalescent Hospital.—Res. M.O. £300.
Cheadle, Cheshire, Cheadle Royal.—Asst. M.O.
City of Westminster Union Infirmary, 369, Fulham-road.—Sen. Asst. M.O. £350.
Coventry and Warwickshire Hospital.—Res. Jun. H.S. £200.
Govan District Asylum, [illegible], Glasgow.—Jun. Asst. M.O. £275.

hand. The percentage of members who are recorded as having received in-patient treatment during the 11 months is 2·083, and the percentage of those recorded as having received out-patient treatment (including dental, massage, and X ray cases) is 8·5.

Although no definite conclusion can be drawn from these figures they are suggestive and encouraging. The number of members of the scheme is still small, and for a large proportion of them the services will be available without further payment during part of next year. On the other hand, as the scheme is becoming more generally known the number of new members joining every month is showing a steady increase, and if this should continue there cannot be a doubt that the success of this year will be repeated and increased in the future.

I am, Sir, yours faithfully,
SELBY,
Hon. Sec., Sussex Provident Scheme for Hospital
Dec. 5th, 1921. and Specialised Medical Services.

The Services.

ROYAL NAVAL MEDICAL SERVICES.

Surgn. Lieut. L. W. Gemmell to be Surgn. Lieut.-Cmdr.

ROYAL ARMY MEDICAL CORPS.

Capt. J. A. W. Ebden, from Res. of Off., R.A.M.C., to be Capt.

The undermentioned Lts. (temp. Capts.) to be Capts: J. D'Arcy Champney, V. J. Perez.

Temp. Capt. (actg. Lt.-Col.) G. Clarke relinquishes his commn. and is granted the rank of Lt.-Col.

R. W. Shaw to be temp. Lt.

ARMY DENTAL CORPS.

Lt. (temp. Capt.) B. W. Tyson to be Capt.

SPECIAL RESERVE OF OFFICERS.

The undermentioned relinquish their commns.: Maj. J. M. Darling (retains the rank of Maj.), and Capts. H. W. Hills (granted the rank of Maj.), J. R. Crolius (on appt. to a commn. in the R.A.F.), and H. F. Vellacott (retains the rank of Capt.).

TERRITORIAL ARMY.

Capt. J. D. Fiddes to be Maj.

Capt. R. V. Favell and is granted the rank of Maj.

Capt. J. R. Griffith (late R.A.M.C.) to be Capt.

Capts. A. R. Grant and N. G. H. Salmon resign their commns. and retain the rank of Capt.

Lt.-Col. C. Graham-Grant, having attained the age limit, is retired and retains the rank of Lt.-Col., with permission to wear the prescribed uniform.

Maj. J. E. Bates, having attained the age limit, is retired and is granted the rank of Lt.-Col., with permission to wear the prescribed uniform.

Maj. A. F. Rutherford, having attained the age limit, is retired and retains the rank of Maj., with permission to wear the prescribed uniform.

Capt. P. H. Mitchiner is restored to the estbt.

The undermentioned officers relinquish their commns. and retain their rank: Majs. J. Allan, W. Y. Martin, F. B. Jefferiss, and R. Thornton (with permission to wear the prescribed uniform); and Capts. D. R. Harris, W. J. H. Davis, and J. Cook.

1st Lond. (C. of L.) Genl. Hosp.—Lt.-Col. (Bt.-Col.) H. J. Waring resigns his commn. and retains his rank.

4th Lond. Genl. Hosp.—Capt. C. Ogle, having attained the age limit, is retired and retains the rank of Capt.

TERRITORIAL ARMY RESERVE.

Col. W. Ranson, from Genl. List, to be Col.

Lt.-Col. A. E. Kidd, from 1st Casualty Clearing Station, to be Lt.-Col.

Capt. A. Ramsbottom, from Genl. List, to be Lt.-Col.

Capt. J. F. Ward, from R.A.M.C., Genl. List, to be Capt.

Maj. J. Nightingale, having attained the age limit, is retired and is granted the rank of Lt.-Col., with permission to wear the prescribed uniform.

ROYAL AIR FORCE.

T. J. D. Atteridge is granted a short service commission as a Flying Officer.

Lt. (temp. Capt.) G. W. Allen, Army Dental Corps, is granted a temporary commission as a Flight Lt. while attached for Royal Air Force duty.

Obituary.

THOMAS GAMBIER, M.D. ST. AND.

THE history of the Eversfield Chest Hospital at St. Leonards is to a great extent the history also of the life of its founder, Dr. Thomas Gambier, whose death occurred on Nov. 27th in his eighty-fifth year.

The third son of George Gambier, of Canterbury, he was at the youthful age of 15 articled to a country surgeon, and then held posts as assistant house surgeon and dispenser at the Kent and Canterbury Hospital. In October, 1858, he entered the Middlesex Hospital, where he gained three years later one of the resident appointments in competitive examination. During his studentship young Gambier took an active part in the resuscitation of the Medical Society attached to the hospital, becoming its secretary and later a vice-president. In 1863 he embarked upon private practice at Okehampton, where he was appointed Poor-law officer and public vaccinator. In 1880 he became clinical assistant at the Throat Hospital, Golden-square, casualty surgeon on the L. & N.W.R., and surgeon-in-charge of the men engaged in boring the Primrose Hill tunnel.

During the early years of his career Dr. Gambier lost a brother and sister from tuberculosis, and it was this domestic sorrow which caused him to devote most of his life to the study of this disease. In 1882, after moving to St. Leonards, he opened at No. 6, Trinity-street, Hastings, a small dispensary for diseases of the throat and ear. Patients were numerous and larger premises were soon needed. While negotiating for a larger hospital, Gambier received, through a moribund patient, a letter from Mr. Samuel Morley, M.P., enclosing a cheque for £20, and she asked that a notice of the gift should be sent to the *Hastings Observer* before she died. The immediate outcome was the raising of a sum of money sufficient to buy the large semi-detached house at Maze Hill, St. Leonards, which was opened in 1884 as the Friedenfels Home. The next stage was the offer, by the late Mr. C. G. Eversfield, of a piece of land on an ideal site at St. Leonards, on which, in 1891, the present Eversfield Chest Hospital was opened. Of this hospital Dr. Gambier was honorary physician and resident medical superintendent until the day of his death, his unceasing labours being recognised by his old friends and patients in 1907, when a life-size portrait by Mr. L. Carr Cox was presented to him.

Dr. Gambier was descended from an old Huguenot family, former members of which left Normandy on the revocation of the edict of Nantes, and he was himself a fellow of the Huguenot Society of London. He leaves a widow who, as secretary of the hospital, rendered him every assistance in his work.

WILLIAM HENRY HADEN-HADEN,
M.D. ST. AND., M.A., D.C.L., M.R.C.S.

Dr. Haden-Haden died on Nov. 20th at the age of 90, and according to his oft-repeated injunction to his friends, his body was cremated. He received his medical education at Guy's Hospital, and at Edinburgh, Cambridge, and Vienna, qualifying, in 1857, with the M.R.C.S. Eng. and graduating M.D. at St. Andrews University in the same year. Dr. Haden-Haden held the appointments of clinical assistant and prosector of anatomy at Guy's Hospital, and was subsequently externe at the Hôtel Dieu and Hôpital des Enfants, Paris, and interne at the Hôpital Lourcine. Later he became hon. physician to the South Dispensary, Liverpool. He was a Fellow of the Medical Society of London, an associate of the Société de Biologie and the Société d'Anatomie de Paris, a member of the Psychological Society of Vienna, and of the General Council of the University of St. Andrews. Though Dr. Haden-Haden confined once, without harm to his health or working-power. Another example of the working of prejudice is the fact that even in London one would have great difficulty in finding a grocer's shop where brown rice could be obtained. Rice-polishing owes its rise to the unwarrantable preference of the public for beautiful white rice. The rice-huller, as a good man of business, trades on this preference, the more so as he knows what to do with the bran. In polishing the rice he deprives it of the silverskin or pericarp—he calls this *refining* it—which, as experience in the tropics has taught us, prevents the outbreak of the much-feared beri-beri. Again, the so-called hard spring wheat is, for more than one reason, preferable to the soft variety, but is so hard and brittle that the husk breaks in little particles, which cannot be separated from the flour by sifting. The dark meal produced dark-coloured bread, which was not wanted because of the popular preference for very white bread; the hard wheat apparently had no future in front of it—it did not fetch its price, and the flat market in its turn depreciated the value of land specially fit for culture of hard wheat. This incited technicists to improve the methods of grinding; mills were made with steel rollers, with which it was possible to get pure white flour from hard wheat also; although it was inferior in nutritive quality to the dark flour, it found a ready market. It goes without saying that much advantage is taken of these public preferences. To please the eye of the consumer manufacturers have begun bleaching meal by chemical means which are not above suspicion. Those familiar with the history of popular nutrition know how obstinately the people will resist new articles of food. It has taken the potato a couple of centuries to secure a permanent place on the table of the people; at present they are so much attached to it that, during the war, people—in Holland at least—preferred bad potatoes to good peas and beans. The indigent population of the occupied regions of Belgium refused to eat the maize of the Relief Committee because they considered it an inferior food, fit only for cattle. In Holland, where the price of meat is extremely high, it is exceedingly difficult to persuade the public to eat the much cheaper, and at least equally nourishing, chilled or frozen Argentine meat.

The question of the quality of food has become much more urgent than the question of quantity; it has frequently been pointed out by such men as Liebig, G. J. Mulder, Donders, Voit, Rubner, that nutrition of the people is a Government concern, but it cannot be said that their warning voice has found much response in their Governments. It seems that catastrophes such as famine or war are necessary to open the eyes of those who are set above us. Under the pressure of the world-war, scientific bodies have been formed, as in England the Food Investigation Board, in the United States the National Research Council, in the Netherlands the Committee of People's Welfare and the Netherland Institute of Nutrition, whose task it is to solve, with the assistance of science, the most urgent problems of society, and in the first place that of nutrition. This is a great step forward. Let us hope that the Governments will also make it possible for these bodies to subsist in times of peace.

Propagandist Measures.

In the United States, for many years past, a propaganda has been carried on by the State and by private people which may, in many respects, serve as an example to Europe. Nowhere, except in Germany, are found so many scientific investigators who serve industry; the practical sense of the people is reflected in the work of its scientists upon problems, the solution of which promises direct profit. This explains why such men as Armsby, Francis Benedict, McCollum, Graham Lusk, Lafayette Mendel, and Thomas Osborne have worked in the field of dietetics.

It would be easy to fill a volume with the enumeration and description of the ways in which, in the United States, propaganda is made for rational feeding. It moves in all directions, and uses means which are still too new for us, but which, for their efficiency, deserve our full attention. Popular scientific literature, the means to which we restrict ourselves in Europe, is used in the United States on a very much larger scale than with us for the purposes of propaganda. Government institutions—e.g., the Department of Agriculture, under which fall the Office of Home Economics, the Bureau of Fisheries, and the Bureau of Markets—distribute gratis or for a small sum, quantities of illustrated pamphlets written by experts, on the most important subjects of agriculture. stockbreeding, home economics, markets, trade, and industry. Charitable societies also do much in this way. Large industrial bodies and companies follow suit, their own interests being best served by the enlightenment of the public. The duties of the 11,000 agents of the Metropolitan Life Insurance Company include the distribution of popular hygienic publications, for which the company has started a printing office of its own. But though this work is very useful, it is by no means considered sufficient because it does not reach all the groups of society, but only those who are susceptible to reason and who are more cultured. The majority take more delight in bioscopes and detective stories.

The North American is much freer in the choice of his means of propaganda than we, who are more careful to observe the proprieties from an exaggerated fear of making ourselves ridiculous. A master of advertisement, he is never at a loss to find a catching phrase, a slogan, to rouse enthusiasm. What would be said in Europe of a clown coming to a school to entertain the children with jokes on the drawbacks of eating sweets and the advantage of drinking milk? Or to a fancy-dress procession in the public streets in the manner of the Boys' Loyalty Parade, recently held in New York, in which "Good Old Milk Bottle" drove before him Teapot and Coffee-pot, the two thieves of children's health, and in which marched a group of useful vegetables—Charlie Carrot, Bill Beet, &c. Such a show, however absurd it may seem, makes a deeper impression than many a learned demonstration, to which, for that matter, the man and the woman and child in the street would not come to listen.

A favourite means of propaganda in the United States is the poster, which has come up to a high standard as regards expression and suggestion.

Club Work among Young People.

In the United States many boys and girls between the ages of 10 and 18 wear a badge, representing a four-leaved clover on which are four H's, and indicating membership of a boys' or girls' club and willingness to work with Hand, Head, and Heart for Health. This quite American organisation of boys' and girls' clubs is a proof of public spirit, insight, and education, organising talent, and enthusiasm. The Smith-Lever Law has in view the giving of useful advice and helpful information to the population on agricultural and domestic affairs; the authorities could hardly have found more diligent and willing assistants for their propaganda than among the young, who, still unprejudiced, learn while they play, and like to imitate the work of their elders. This inborn tendency of children the States Relation Service, a subdivision of the Department of Agriculture, has turned to account, of course in concert and collaboration with the school authorities, and has attained results of great importance to the State and to the family. The Extension Service works among the young, through club leaders, home demonstrators, and specialists in various agricultural and domestic industries, who promote the starting of clubs, the members of which apply themselves, under their guidance, to the cultivation of useful plants, the breeding of cattle and fowls, to fruit-preserving, cooking, domestic work, &c., on a small scale and in accordance with local requirements. It is stated in the 1918 report, by the director of the States Relation Service, Mr. A. C. True, that club work has produced 825,000 bushels of maize, 680,000 bushels of potatoes, 2,000,000 quarts of preserved food, 1,922,300 fowls, 908,000 dozen eggs, 824,000 lb. of meat, 1,668,900 lb. of cotton, not to speak of other products, such as jelly, peanuts, sorghum, wheat, and beans. The greater part of this produce has been used for domestic purposes, and has saved much outlay in the first necessaries of life; no small part of it has yielded immediate profit. I shall not tire you with specific instances, but will only say that the gain has enabled many a one to defray his college expenses. Nor should the indirect advantage of club work be rated low, for the profit gained cannot but impress the older people; their attention is drawn to new and improved methods.

I hope you will not suspect me of imagining that American club work is fit for wholesale transplantation to our own continent. The difference in economic circumstances between the Old World and the New is too great for this. Where, for instance, would one find in our densely populated countries so many pieces of fallow land, fit to be made a loan of to boys' and girls' clubs? But though an unconsidered imitation of the North-American institution of boys' and girls' clubs is out of the question, I believe that much good may be done by introducing it on a small scale.

The Transplantable Dietician.

The calling of the dietician might be transplanted to our European society without much alteration, and would greatly benefit the cause of feeding the people. The recent development of work for the improvement of defective social conditions has not hitherto included propaganda for rational feeding—chiefly owing to the fact that there are no experts who could be entrusted with this work. In North America dieticians have existed for years, and anyone who has seen them at work there asks himself how it is possible that, up to now, we in Europe have had to do without their good services. The work of dieticians cannot be described in a single word, for several categories must be distinguished—categories of medical dietetics, domestic economy, poor relief, charity; in short, wherever problems of feeding wait for solution.

I first made the acquaintance of the dietician in Battle Creek Sanitarium, the largest of the kind of the United States and probably of the world, where thousands of more

The Bradshaw Lecture of the Royal College of Surgeons of England will be delivered by Mr. H. J. Waring, on Wednesday, Dec. 14th, at 5 P.M., on the Operative Treatment of Malignant Disease: its Possibilities and Limitations.

Royal Hants County Hospital. — At the quarterly court of governors of the Royal Hants County Hospital, Winchester, it was reported that last year nearly £1000 was raised by the weekly insurance scheme, which was meeting with great success. It was stated that the re-modelling of the X ray department was in hand at a cost of £1000.

West Kent Medico-Chirurgical Society.—A meeting will be held at the Miller Hospital, Greenwich, to-day, Friday, Dec. 9th, at 8.45 P.M., with Dr. C. T. T. Comber, the President, in the chair, when the Purvis Oration will be delivered by Sir James Purves Stewart on Respiratory Disorders of Nervous Origin.

University of Bristol.—Sir Isambard Owen having retired from the Vice-Chancellorship of the University, an office of which he was the first occupant, the Court of the University has conferred on him the title of Honorary Fellow. He is succeeded as Vice-Chancellor by Principal Loveday, of Hartley University College, Southampton.

Pharmaceutical Society of Great Britain.—A meeting of this society will be held at 17, Bloomsbury-square, London, W.C., on Dec. 14th, at 8 P.M., when Prof. H. G. Greenish and Miss C. E. Pearson will present a communication from the Research Laboratory of the Society on Volatile Oils in Pills, and Mr. T. E. Wallis, lecturer in botany, will discuss Moths (Corcyra, Ephestia, and Borkhausenia) as Pests. The meeting will be social as well as scientific in character, and medical friends of members are cordially invited.

Panel Committee for the County of London.—The second annual local medical and panel committee dinner and dance will be held at the Holborn Restaurant on Thursday, Dec. 15th, at 7 P.M. Mr. R. W. Harris, Dr. Smith-Whitaker and Sir Thomas Neill, J.P., will be guests of the evening and will speak. All practitioners whether on the panel or not will be welcomed. Tickets (gentlemen 21s., ladies 15s., exclusive of wine) may be obtained from the Secretary, Mr. Robert J. Farman, Staple House, 51, Chancery-lane, London, W.C. 2.

Bristol Medical School: Annual Dinner.—The annual dinner of the Bristol Medical School was held on Nov. 28th, Mr. W. R. Ackland presiding. The health of Sir Henry Gray, the guest of the evening, was proposed by Dr. R. C. Clarke, who alluded to the value of the services rendered by him to the armies in France. In his reply Sir Henry Gray drew attention to certain similarities between the Aberdeen and Bristol schools of medicine, and paid a tribute to the practical and thorough spirit shown of the Bristol men whose work he had seen in France. The dinner was preceded by the Long Fox lecture on the Repair of Bone Injuries, by Mr. E. W. Hey Groves.

London (R.F.H.) School of Medicine for Women Dinner.—A successful function, at which about 250 past students, students, and guests assembled, was held at the Connaught Rooms, Great Queen-street, London, W.C., on Dec. 2nd. Mr. James Berry presided, and in a speech, which reflected his pride in and affection for a medical school which he had done so much to develop, proposed the toast of the Royal Free Hospital and the London School of Medicine for Women. Mr. Berry congratulated the authorities on the establishment of the first clinical unit in obstetrics and gynæcology. This had been made possible by the generosity of Lady Barrett, who, though unable to spare the time from her consulting practice to undertake the duties of director, had relinquished her beds in the hospital to Prof. Louise McIlroy. He spoke of the examination successes of the past year, two old students having become F.R.C.S., and one having gained the gold medal in the M.B., B.S. Lond.; and urged the resumption of two characteristic features of the Royal Free Hospital teaching which had lapsed during the war—consultation over cases and an annual exhibition of museum specimens. In welcoming the new members recently appointed to the honorary staff of the hospital, Mr. Berry emphasised the importance of research as well as good routine work among the duties owed to a hospital by its staff. The toast of the guests of the evening was proposed by Dr. Haldin Davis, and that of the chairman by Mrs. Lucas Keene, both in happy anecdotal vein. Sir Arthur Keith responded for the guests and Mr. Berry for himself. An excellent feature of this dinner was the limitation in number and length of the speeches in order to leave time after the formal proceedings for old friendships to be renewed.

Civic Education League.—A lecture will be given on Thursday, Dec. 15th, at 8.15 P.M., at Leplay House, 65, Belgrave-road, S.W. 1, by Dr. C. W. Saleeby, entitled Light Against Death. The chair will be taken by Dr. Gladys Miall Smith. Admission will be free.

Dr. C. W. Paget Moffatt has been appointed medical officer of health for Bolton.

Small-pox in Colne Valley.—Five cases of small-pox have been notified to the Marsden Urban Council during November. Altogether about 50 cases have been notified in the Colne Valley recently.

Donations and Bequests.—The Board of Management of the Royal Infirmary, Manchester, has received from Messrs. Peel and Co. £750 for increase of endowment of a bed, from Mr. and Mrs. George Bolton Stott £125 10s. for purchase of an operating table, and over £350 from various commercial firms and other donors.

North-Western Tuberculosis Society.—A meeting of this society will be held at the Public Health Laboratory, York-place, Manchester, on Thursday, Dec. 15th, at 3 P.M., when Dr. Arthur Sellers will read a paper on Complement-Fixation Tests in the Diagnosis of Tuberculous Infections. Any medical practitioner interested in tuberculosis is invited to attend.

Voluntary Hospitals and the Ministry of Health.—In a long letter to the *Times* of Dec. 7th Sir Alfred Mond justifies the policy of the Government in asking voluntary hospitals to coöperate in raising fresh revenue. Unconditional deficiency grants would, he says, have been a sure way of relaxing voluntary effort. He announces a considerable amount of "new money" in sight; at least £100,000 a year is expected from the approved societies, and other schemes for London are being developed by the King's Fund. The Minister of Health states advisedly that what has been done should be adequate, if the community also plays its part, to save the voluntary system.

A Post-graduate Course in London.—The Fellowship of Medicine and Post-Graduate Medical Association, with the coöperation of various special hospitals, is arranging to hold in the metropolis a series of special courses in general and special subjects during the forthcoming year. These will begin with a six weeks' post-graduate course in medicine from Jan. 9th to Feb. 18th, 1922, when both morning and afternoon sessions will be held at various special hospitals. This has already been announced in our columns, and the titles of the subjects to be dealt with by the various lecturers will be published shortly. The fee for the course will be 15 guineas, and as the numbers attending will be limited to 20, early application should be made to the Secretaries of the Fellowship, 1, Wimpole-street, London, W.1.

Paddington Infirmary: Opening of Nurses' Home.—On Dec. 5th Lord Onslow formally opened a new nurses' home and spacious operating theatre at the infirmary in Harrow-road. Before the ceremony, Mr. H. A. Baker, Chairman of the Board of Guardians, outlined the development of the existing infirmary from an old-fashioned Poor-law workhouse and infirmary of ten years ago into a modern well-equipped hospital, wherein 218 serious operations were performed and 1000 X ray examinations made last year. Lord Onslow, in declaring the buildings open, laid particular stress on the value to all concerned of the coöperation between infirmaries and voluntary hospitals, such as existed between this infirmary and St. Mary's Hospital. He congratulated the nursing profession in general on the adoption of shorter hours for nurses, expressing his firm belief in the benefit to patients as well as to nurses resulting from less fatiguing conditions of work for the latter. Mr. L. V. Lester-Garland, Chairman of the Building Committee, gave details of the construction of the new buildings and incidentally described a deputation to the Ministry of Health when the proposals were first considered. He said that this department, like other Government departments, was imbued with much caution and had refused to commit to paper any statements of approval except to promise that the Ministry of Health would "take an intelligent interest" in the scheme. A vote of thanks was proposed to Lord Onslow by Mrs. H. Jones, Chairman of the Infirmary Committee, and seconded by Mr. W. Day, Vice-Chairman of the Finance Committee. The buildings, designed by Mr. Percy Adams, F.R.I.B.A., were open for general inspection, the operating theatre being a special feature of the up-to-date equipment. A large communicating corridor has also been erected connecting the central building to the kitchen and other blocks. The speakers were unanimous in their appreciation of the energetic and untiring action of Dr. A. G. Stewart, the medical superintendent of the infirmary, in promoting the rapid development of these valuable additions to the infirmary.

much lower than was anticipated, and the degree of infection, estimated by the number of worms removed, less. The cases of ankylostomiasis allowed in the Soudan will receive further treatment at their working destination. On the other hand, the percentage of bilharziasis is very much higher, and if all cases were rejected recruiting of Said labour would be an impracticable proposition. For this reason, and taking into consideration that bilharziasis is already very widely distributed throughout the Soudan, it has been decided to reject only severe cases of this disease and to allow others to be employed on the Gezira works until the canal system is much further advanced than at present, when the risk of spreading infection will be increased and the question will have to receive further consideration.

The parts of the country affected by sleeping sickness are Western Mongolla and Southern Bahr-el-Ghazal. In the former the campaign against the sickness has been in progress some ten years. Its general situation can best be described by saying that the disease is under control. During the time the restrictions of quarantine, &c., have been in force a marked improvement has taken place. In the Southern Bahr-el-Ghazal the work has been in progress for not more than about three years. Latterly the death of Captain A. Watson, D.S.O., R.A.M.C., has left the district with only one medical officer. A new camp has been formed near the French equatorial frontier. It seems to be the case that the system of segregation in practice in Western Mongolla is likely to prove the best method of ultimately eradicating the disease from the Soudan.

LICENSED BIOLOGICAL PRODUCTS IN U.S.A.

IN July, 1902, Congress approved "An Act to regulate the sale of viruses, serums, toxins, and analogous products in the District of Columbia, to regulate interstate traffic in said articles, and for other purposes." *Public Health Reports* for Oct. 14th contains a list of the establishments holding licences issued by the Treasury Department in accordance with this Act. The list is as follows:—

Parke, Davis and Co., Detroit, Mich.; H. K. Mulford Co., Philadelphia, Pa.; Sleo Laboratories, Surftwater, Pa.; the Cutter Laboratory, Berkeley, Calif.; Bureau of Laboratories, Department of Health, New York City; Lederle Antitoxin Laboratories, Pearl River, N.Y.; Bacterio-Therapeutic Laboratory, Asheville, N.C.; Dr. G. H. Sherman, East Jefferson-avenue, Detroit, Mich.; Hygienic Laboratory, California State Board of Health, Berkeley, Calif.; the Abbott Laboratories, 4735, East Ravenswood-avenue, Chicago, Ill.; Beebe Laboratories, St. Paul, Minn.; Dr. W. T. McDougall, 640, Minnesota-avenue, Kansas City, Kans.; St. Louis Pasteur Institute, 3514, Lucas-avenue, St. Louis, Mo.; the Upjohn Co., Kalamazoo, Mich.; E. R. Squibb and Sons' Research and Biological Laboratories, New Brunswick, N.J.; Laboratory of Clinical Pathology, 1208, Wyandotte-street, Kansas City, Mo.; Dr. James McI. Phillips, 2057, North High-street, Columbus, Ohio; Eli Lilly and Co., Indianapolis, Ind.; Swan Myers Co., 219, North Senate-avenue, Indianapolis, Ind.; Gilliland Laboratories, Ambler, Pa.; Antitoxin and Vaccine Laboratory, Department of Public Health, Commonwealth of Massachusetts, Forest Hills, Boston 30, Mass.; United States Standard Products Co., Woodworth, Wis.; D. L. Harris Laboratories, Metropolitan Building, St. Louis, Mo.; the Arlington Chemical Co., Yonkers, N.Y.; Dermatological Research Laboratories, Philadelphia, Pa.; H. A. Metz Laboratories, 122, Hudson-street, New York City; Synthetic Drugs and Diarsenol Laboratories, Buffalo, N.Y.; Hynson, Westcott, and Dunning, Baltimore, Md.; Mallinckrodt Chemical Works, St. Louis, Mo.; Empire State Chemical Laboratories, Brooklyn, N.Y.

Seven foreign establishments also appear on this list. In some cases the licence is issued for a single product—e.g., arsphenamine or rabies vaccine; in others, for 50 preparations or more. One of the longer enumerations is the following:—

Diphtheria antitoxin; tetanus antitoxin; perfringens antitoxin; antianthrax serum; antidysenteric serum; antigonococcic serum; antimelitensis serum; antimeningococcic serum; antipneumococcic serum; antistreptococcic serum; normal horse serum; vaccine virus; rabies vaccine; tuberculin old; tuberculin T.R.; tuberculin B.E.; tuberculin B.F.; tuberculin proteose-free (Lyons); bacterial vaccines made from acne bacillus, cholera vibrio, colon bacillus, dysentery bacillus, Friedländer bacillus, gonococcus, influenza bacillus, meningococcus, micrococcus catarrhalis, micrococcus melitensis, paratyphoid bacillus A, paratyphoid bacillus B, pertussis bacillus, plague bacillus, pneumococcus, pseudodiphtheria bacillus, staphylococcus albus, staphylococcus aureus, streptococcus, and typhoid bacillus; sensitised bacterial vaccines made from acne bacillus, cholera vibrio, colon bacillus, Friedländer bacillus, gonococcus, influenza bacillus, meningococcus, micrococcus catarrhalis, paratyphoid bacillus A, paratyphoid bacillus B, pertussis bacillus, pneumococcus, pseudodiphtheria bacillus, staphylococcus albus, staphylococcus aureus, streptococcus, and typhoid bacillus, diphtheria toxin-antitoxin mixture; pollen extract.

The licences granted do not imply an indorsement of the claims made by the manufacturers for their preparations. The granting of a licence means that inspections of the establishment concerned and laboratory examinations of samples of its products are made regularly to ensure the observance of safe methods of manufacture, to ascertain freedom from contamination, and to determine the potency of diphtheria antitoxin, tetanus antitoxin, antidysenteric serum, antimeningococcic serum, antipneumococcic serum, bacterial vaccines, prepared from typhoid bacillus, paratyphoid bacillus A, paratyphoid bacillus B, and diphtheria toxin-antitoxin mixture, the only products for which potency standards or tests have been established.

CYNOTHERAPY.

To the Editor of THE LANCET.

SIR,—In your issue of Nov. 26th under this heading a correspondent gives a recipe for dog oil copied from Pharmacopœia Londinensis, 1659, containing in its ingredients "sallet oyl, two puppy dogs newly whelped, earth worms washed in white wine, and cypress turpentine and spirit of wine."

It is interesting to compare this with the following copied from "Confessio Medici,"[1] quoting from writings of Ambroise Paré about 1540. "When I was at Turin I found a surgeon famed above all the rest for his treatment of gunshot wounds; into whose favour I found a way to insinuate myself, that I might have the recipe of his balm as he called it, wherewith he dressed these wounds. And he made me pay my court to him for two years, before I could possibly get the recipe out of him. In the end, thanks to my gifts and presents, he gave it to me, which was this, to boil down, in oil of lilies, young whelps just born, and earthworms prepared with Venice turpentine. Then was I joyful and my heart made glad, that I had learned his remedy."

I am, Sir, yours faithfully,

EDGAR J. TYRRELL.

Pope's Head Alley, Cornhill, E.C. 3, Dec. 3rd, 1921.

NEWSPAPER INSURANCE.

FOR some time past various newspapers have offered advantages to their readers in the way of insurance against railway accidents and other sudden and expensive calamities. As far as we remember the practice began with the promise of a sum of money to the representatives of a person found dead after a railway accident with a copy of a particular publication in his pocket. This, however, was obviously not an inducement to subscribe regularly, and there was no certainty that the person who bought the paper and met with an accident would so dispose of it that he could be identified with it, and his dependents enabled to make a claim. The insurance now offered usually takes the form of an order given to the newsvendor (who himself receives a commission when any compensation is paid) combined with the registration of the subscriber's name by the newspaper. The benefits promised have also been largely increased. A single subscription in at least one instance secures advantages to a husband and his wife. The accidents insured against include many varieties besides those encountered when travelling by rail or motor-car. Even accidents in the home or in the football field can be provided against.

We do not criticise or inquire into the soundness of such schemes from the actuary's point of view. The newspaper deliberately adopts an expensive, but no doubt also an effective, means of advertising itself and of increasing its circulation. The subscriber benefits by such perfectly legitimate enterprise. If he has no special preference for a particular journal as "mental pabulum" he no doubt will be careful to choose the one that offers him the greater advantages, taking account of the ordinary risks to which he and his wife are subject. Medical men who are witnesses of the strain put upon the finances of their less wealthy patients when an accident occurs should be first to commend an inexpensive method for meeting it. Medical men themselves encounter not only the ordinary risks of citizens, but others more or less incidental to their calling. They also, and their families, belong to the class to which the reading of a daily newspaper is practically a necessity of life.

There is another class of insurance which newspapers might well offer, either as an alternative to or jointly with other risks. We refer to that which the National Provident Scheme for Hospital and Additional Medical Services is designed to provide for persons whose incomes do not exceed £500 per annum. At a meeting to consider the National Provident Scheme held by the British Medical Association, Marylebone division, Dr. A. Cox expressed a preference for a "straightforward insurance scheme." Such a scheme might well include persons of all classes and incomes who, in the case of serious illness or operation, would receive compensation or contribution based upon the reasonable expenses of their treatment and proportionate to the premiums paid. It would not, of course, in the case of those not treated in voluntary hospitals, have any effect upon hospital finance, but would be the concern of the lay public and the actuaries. The newspapers, having insurance schemes, would be able to take such part as they found to be consistent with their objects and interests.

West London Hospital, Hammersmith-road.—Two H.P.'s and one H.S. Each £100.
West Middlesex Hospital, Isleworth.—Asst. Med. Supt. £300.
Willesden Urban District Council.—Obstet. and Gynæcol. 100 guineas.

The Chief Inspector of Factories, Home Office, S.W., gives notice of vacancies for Certifying Surgeons under the Factory and Workshop Acts at Chirk, Menai Bridge, and at Chippenham.

The Home Secretary gives notice of a vacancy for a Medical Referee under the Workmen's Compensation Act, 1906, for the Margate and Ramsgate County Courts in Circuit No. 49. Applications for the post should be addressed to the Private Secretary, Home Office, and should reach him not later than Dec. 28th.

Births, Marriages, and Deaths.

BIRTHS.

Pridham.—On Nov. 29th, at Hillfield, Broadway, Dorset, the wife of Dr. J. A. Pridham, M.C., of a daughter.

Troup.—On Dec. 2nd, at "Morning Dawn," Cooden, the wife of Dr. W. Annandale Troup, M.C., of a son.

MARRIAGES.

Coats—Hutchinson.—On Dec. 1st, at St. John's Church, Paddington, Captain Douglas Hamilton Coats, R.A.M.C., to Eileen Constance, daughter of Lieut.-Col. F. H. G. Hutchinson, I.M.S.

DEATHS.

Doyle.—On Nov. 28th, at 203, Colcherne-court, Lieut.-Col. Bernard Doyle, late I.M.S., aged 71 years.

Haines.—On Nov. 30th, at his residence, 12, Old Court-mansions, Kensington, W., Charles Henry Haines, M.A., M.D., F.R.C.S.

Hogg.—On 3rd inst., at Ealing, Arthur John Hogg, M.R.C.S., F.R.C.P.E., in his 73rd year.

Hugo.—On Nov. 29th, after a short illness, at his residence, Richard Mandeville Hugo, M.D., F.R.C.S.I., in his 58th year.

MacQueen.—On Dec. 1st, suddenly, at Bolton House, Bolton-road, Eastbourne, Thomas MacQueen, M.B., C.M. Edin., aged 70 years.

Meldrum.—On Nov. 10th, at 23, Montpelier, Hyde Park, Leeds, J. W. Meldrum, M.A., of the Leeds Central High School, dearly beloved husband of May I. T. Meldrum, M.B., D.P.H., Leeds Public Health Department.

Rossiter.—On Nov. 27th, at Cairo Lodge, Weston-super-Mare, George Frederick Rossiter, M.B. Lond., M.R.C.S. Eng., aged 69 years.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

DIETETICS AND PUBLIC HEALTH.[1]

By Prof. E. C. Van Leersum, M.D.,
DIRECTOR OF THE NETHERLANDS INSTITUTE OF NUTRITION, AMSTERDAM.

The Necessity of Systematic Propaganda in Nutrition of the People.

Rational feeding is made difficult by the complexity of modern life. An actual shortage of food need not be feared in the near future, for although our resources are not inexhaustible, they will no doubt suffice for a very long time to come. If the estimations published by the late Sir William Crookes had been correct, we should now have begun to be aware of the shortage of wheat predicted by him; but, on the contrary, notwithstanding the rapid increase of population, production has proved sufficient to supply the needs of that part of it that is accustomed to eat bread. Moreover, a shortage of wheat would not mean an irremediable disaster; at the worst bread-eaters would have to reduce their ration of palatable white bread, but would then be no worse off than their forefathers who also used to take other materials besides wheat and rye to make their bread and cakes—viz., spelt, millet, barley, buckwheat, oats, rice, and even beans. All that is needed is technical improvements in baking, through which, sooner or later, a means will doubtless be found to render these kinds of flour, which owing to their smaller percentage of gluten are not yet used for the baking of aerated bread, fit for that use.

Without wishing to underrate the value of white bread as food for the Caucasian race, I do not believe that the food problem in general depends on it. Immeasurable stretches of land still lie fallow and wait to be cultivated in order considerably to increase the present production of grain and other foodstuffs, which has not nearly reached its maximum on the land already cultivated. There is no reason to fear that science will fall short of our expectations in the direction of agriculture. But pessimistic prophecies like that of Prof. Crookes have at least this advantage, that they rouse men and set them to work to avert the foretold disaster.

International Trade in Foodstuffs.

The rise in price of many foodstuffs is by some people wrongly regarded as a sign that dearth is coming; this dearness is really attributable to other causes. If in fertile Holland tree-fruit has become so dear that the poorer part of the population have to go without it, it is not because of a shortage of fruit or of orchards, but rather because of the operations of trade—i.e., the finding of more profitable markets elsewhere. Many foreign and overseas foods have become indispensable to us, so that we should have to rack our brains to compose a meal of nothing but home products. Not to speak of tea from Ceylon and Java, coffee from Brazil, and cacao from the West Indies, our breakfast bread is baked of flour from Canada or the United States; our bacon or ham have, I daresay, been supplied by Swift or another of the big five; our beef has probably been imported from the Argentine, our mutton from Australia—or if not, our cattle have most likely been fattened with Argentine linseed meal and North American maize. As for cake, the confectioner is not likely to have made it with expensive home eggs, for China can supply him with much cheaper dried white and yolk. And the artificial butter which he has used finds its origin in the fat of American cattle or in the palm seeds or cocoa-nuts from tropical regions. Now, if we still lived in the primitive state of Nature we might allow instinct to guide us, as it did successfully when dietetics were unknown; but in our present society this instinct has no chance to develop and can no longer serve us. We are bound by social circumstances which do violence to our Nature; the obstacles in the way of rational feeding are partly economic, but are also found in ignorance, false notions, prejudice, intemperance. The war emphasised what we knew partially before through scientific experiments—that we can do with much less food than we thought we could; but that lesson is already forgotten again, and most people eat to their hearts' content, without bothering about economy or health.

Prejudice in Diet.

Meat is the most desirable food in the eyes of the poorer classes, and in many a workman's household more is spent on meat than the income justifies; the North American workman is not satisfied unless he has meat on his table twice or three times a day, though he might very well do with it

---

[1] Being a Chadwick lecture given at the Barnes Hall, Royal Society of Medicine, on Nov. 24th.

The Origin
OF THE
ANGINAL SYNDROME.

A Paper read at the Opening of a Discussion of the Harveian Society on Dec. 8th, 1921,

BY SIR CHARLTON BRISCOE, BART.,
M.D., F.R.C.P. LOND.,
PHYSICIAN TO KING'S COLLEGE HOSPITAL.

THERE are probably few subjects in medicine which have given rise to more discussion than the pathology of angina pectoris. In such discussions explanation of the mechanism of the pain has always been to the fore; on this particular point of the syndrome (as it occurs in some cases) I purpose to submit some evidence which I believe has not before been produced. Angina pectoris is generally supposed to spring from some event taking place in the heart or aorta; the pain certainly arises in the neighbourhood of the heart and the fully developed attack is notorious as a cause of sudden death.

DEFICIENCIES OF PRESENT KNOWLEDGE.

Yet in spite of long recognition as a clinical entity, in spite of much skilled investigation, the exact cause of these overwhelming outbursts of pain remains uncertain, and we have come to realise the following deficiencies in our knowledge:—

(1) *In Anatomy and Physiology.*—From anatomy we ask the demonstration of afferent fibres to carry pain sensations from the heart, their course, connexions, and termination; from physiology, the function and method of expression of these fibres. Neither branch of science can fully supply the required information. We know that afferent fibres do come from the heart—most, perhaps, passing up by the depressor fibres of the vagus, some to the stellate ganglion, but of the subsequent course of these to and in the cord nothing certain is known. Physiology is indefinite regarding the sensation of pain arising in internal viscera. The current view is that all visceral pain is due to tension (Hurst); knowledge of its external expression is based mainly upon the researches of Dr. Henry Head and may be briefly expressed as follows: The distribution of pain caused by irritation of an internal viscus corresponds with that of a segment or segments of the spinal cord. The internal viscus itself, in this case the heart, has largely lost the capacity to produce sensations directly appreciated by the individual, but afferent impulses pass up from it to a segment or segments of the spinal cord. There they may be said to jangle their neighbours connected to somatic structures, making them hypersensitive, and so producing sensations appreciated in consciousness in the field of distribution of these somatic nerves. Thus various sensations, of which pain is the most prominent, are appreciated by the individual, not in the viscus actually at fault, but in the skin, muscle, subcutaneous tissue, and bone innervated from the same spinal segment. The somatic representation of the various segments of the cord has been systematised mainly through the work of Head and these distributions are generally accepted. A later part of Head's work consisted in correlating certain somatic areas with hypersensitiveness arising from irritation of certain viscera. Finding that the areas of pain in angina pectoris and certain cardiac conditions occurred in the somatic areas of certain segments, Head deduced that the heart was connected to nerve cells in these segments. They are principally dorsal. This deduction has the disadvantage that it is a physiological conception based upon a clinical condition of doubtful pathology; further, in this connexion it is important to remember a phylogenetic consideration—namely, that the heart was originally developed in spinal segments higher than the dorsal, that it migrated caudalward and therefore that somatic areas of referred pain, to correspond with the heart, should be cervical rather than dorsal.

(2) *In Pathology.*—We cannot yet point with certainty to any lesion which can be indicated as a cause of angina. It is possible to argue both for and against aortitis or coronary sclerosis. Most significant in this respect are the theories of functional spasm, cramp of the heart and the like, as indications of a beggared pathology.

(3) *From the Clinical Aspect of Heart Disease.*—Perhaps the most striking fact is the comparative rarity of pain in heart affections, leading to the thought that the heart must be a comparatively insensitive organ. In respect of angina, however, we have a clear-cut picture of the fully developed attack, and we also know a similar condition described as hysterical. More frequent than these, however, are cases fitting neither of them. The true fully developed angina and the so-called false angina are but the extremes of a very large class, the bulk of which in the present state of our knowledge lies intermediately, and causes us great trouble in diagnosis and prognosis.

To sum up our ignorance of angina pectoris, anatomically, we know merely that sensory end-organs do exist in, and afferent fibres do pass from, the heart and aorta; physiologically, we have a conception of heart sensation resting upon a rather insecure foundation; pathologically, we have no certain base to build on; and clinically, we have to deal with a number of ill-defined cases. We lack the knowledge which would enable us to docket the latter.

ANGINA AND STRESS OF SOME RESPIRATORY MUSCLES.

In following up some work concerned with the mechanism of lung expansion, the results of which I brought forward in one of the Arris and Gale Lectures in 1919, I have been constantly testing the action of accessory muscles concerned in respiration. I did not set out to study angina pectoris, but in testing these muscles came upon some facts which compelled my attention in that direction. Briefly put, and before entering into details, what I found was as follows. Some of these accessory muscles varied very much in intensity of action and stress in different positions of the body, and in different circumstances. When under stress these muscles became tender, and—and this is where my thoughts were forced towards angina, —when pressure was made upon these tender muscles the pain produced was not always a mere local sensation, but was referred to wide areas very similar to those concerned in angina. Next I found that in some cases which had suffered from anginal type of pain, pressure on certain of these muscles produced pain like that of the attack, and finally in some cases of angina relief of tension in these muscles was followed by cessation of pain.

Various as are the exciting causes of an attack of angina, they are such as would affect the respiratory apparatus (particularly in the upper part) as much as the cardiovascular. In many cases there are warning sensations referred by the individual to something occurring in the neighbourhood of, and posterior to, the sternum. These warnings generally occur under circumstances of physical strain, and if neglected are followed by an attack, or the attack may come on suddenly during exertion. In both these types there is respiratory stress in which, as in dyspnœa generally, an excessive part is played by elevation of the thorax. An attack may be precipitated by a large meal, when the diaphragm, hindered in action by a distended stomach, throws more work on the upper respiratory muscles, or by emotion, when the same upper thoracic respiratory stress occurs. Finally, attacks frequently come on for no apparent reason when the patient is resting in bed at night. These are difficult to explain on a cardiac basis, but, though not well recognised, it is a fact that the supine posture tends to quiescence of the lower thoracic and abdominal respiratory mechanism at the expense, and consequently with overwork, of the upper thoracic mechanism. An extreme instance of this is seen in the or less serious cases are treated yearly according to physical and dietetic methods. The entire care of the patient's food (complicated in this instance by adherence to vegetarian principles) has there been given into the hands of persons properly instructed in the science of foodstuffs, of digestion and metabolism, and in general and medical dietetics. When I visited Battle Creek I found there no fewer than six dieticians, two of whom were exclusively charged with the supervision of the diabetes kitchen; the latter were—as I had an opportunity of ascertaining—quite equal to this task. At present in most American hospitals of any standing, dieticians are employed, to the great satisfaction of the boards—who make an appreciable financial profit out of this work—of the medical staff, whose task is considerably lightened, and, last but not least, of the patients.

In Europe the problem of feeding in the hospitals has, in spite of its importance, not yet received much attention; the matrons, controllers, administrators, and cooks, to whose care it has been entrusted, are not experts, at best they are amateurs as regards feeding and hospital cooking, while the physician is too much taken up by his professional cares to be always able to supervise the carrying out of his dietetic prescriptions. Why not put an end to this unpractical state of affairs by ensuring the execution of these prescriptions in a way similar to that long since taken with regard to medical prescriptions? That such a course can also be successfully followed in the execution of dietetic prescriptions has been proved by experience in North America. To begin with the scientifically trained and responsible dietician keeps a watchful eye on the quality of the food bought and sees that the preparation of it takes place according to the laws of cookery. In special cases she takes charge herself in kitchens specially designed for the purpose; accompanying the doctor when he visits the patients, she notes down his directions concerning their diet and works out the menus, observing the quantity and quality desired, the proportion of calories, at the same time taking into consideration the particular desires of the patients—for instance, ritual prescriptions, &c. She supervises the preparation and the distribution of the food, finds out how much has been taken, takes note of its effect by means of weighing, examination of excreta, if necessary quantitative test for sugar, and regularly reports the results to the doctor.

"Out-patient Diet."

Outside the hospital, also, sick people can avail themselves of the services of the dietician. Every doctor knows how difficult it is, even where money is no obstacle, to get the more intricate dietetic prescriptions properly carried out. The housewife may do her best, but as a rule a diabetes menu is beyond her powers, partly because she has no idea of the protein, carbohydrates, and fat-content of the ordinary and of the so-called diabetes foodstuffs, partly because the preparation of the food that the patient is permitted to have is too difficult and troublesome.

How far the measures taken by many North-American firms to promote the nourishment of their officials and workmen might be imitated in Europe I dare not decide. In many cases these companies try to accomplish this purpose by giving nourishing and cheap, even free, lunches, to their employees in private lunchrooms and "cafeterias," where they avail themselves of the advice and services of dieticians; but though, in principle, measures of this kind deserve to be applauded, it depends on the financial strength of a business whether there is a possibility of carrying them out.

Training of the Dietician.

This training comprises an extensive curriculum, a prominent place being given to natural sciences, physics, chemistry, botany, and zoology, these being the foundation of the science of foodstuffs, dietetics and metabolism, domestic economy, cookery, and general and special dietetics. The dietician should be not merely a speaking-trumpet, but an expert, who can judge independently, can criticise, and follow the course of dietetics. Intelligence, general education, refinement, and knowledge of men are necessary to ensure for the woman taking up this profession, the necessary moral ascendancy over the less cultured among whom she will have to move; she also requires philanthropy, devotion, and a sense of duty. No more remarkable thing struck me in the United States than the work of the dieticians in the slums. I was allowed to accompany them on their home-visiting, and could admire the tact with which they contrived to win the mothers and to conquer the shyness of the ragged children. There are no better means of convincing the mothers of the utility of milk and other nourishing food and the harmfulness of bad sweets than a rising curve of bodily strength and weight. I have been present at nutrition classes where mothers and children met to have the necessary knowledge inculcated by practical demonstrations. I remember with pleasure such a meeting held in an empty shop in the densely populated Amsterdam Avenue. One of the dieticians began with a chat on some questions of nutrition—giving, for instance, a graphic illustration of the difference in nutritive value of coffee and milk. Then she treated the subject of soup and pointed out the nutritive value of peas and beans; at the end of her pleasant and instructive demonstration we all received a paper mug of bean soup. Then a little poem was written on the blackboard and the audience was asked to sing it. We all sang at the top of our voices to the accompaniment of a guitar:—

> Here's to your good health and mine,
> When short in milk, pea-soup is fine,
> It's hot and good at noon or night,
> Makes muscles strong and faces bright.

Finally the charts were examined on which had been traced the weight-curves of the children and on which some of the children themselves had noted down some hygienic measures. Then the marks of distinction were awarded—coloured paper stars which were pasted on the charts; it was all very simple, even naïve, but all the more effective. To this the faces of the mothers and children bore evidence when the lesson was over.

In conclusion, if I have claimed your attention for a moment for so self-evident and prosaic a thing as nutrition, I have done so for the simple reason that it is the cornerstone of the life and strength of the nation.

> We may live without poetry, music and art,
> We may live without conscience, and live without heart,
> We may live without friends, we may live without books,
> But civilised man cannot live without cooks.
> He may live without books, what is knowledge but grieving?
> He may live without hope, what is hope but deceiving?
> He may live without love, what is passion but pining?
> But where is the man that can live without dining?

EGYPT AND THE SOUDAN:
HEALTH AND SANITATION.

II.—SOUDAN.

THE following completes the summary of the report of Field-Marshal Lord Allenby on the affairs of Egypt and the Soudan for the year 1920.

Soudan Administration.

Turning to the Soudan, the High Commissioner forwards a report from Major-General Sir Lee Stack (Governor-General) on the administration and condition of that country. Under the heading "Public Health," Sir Lee Stack writes that the most important feature has been the severe outbreak of small-pox in the southern provinces — Babr-el-Ghazal, Mongolla, Upper Nile, and Nuba Mountains—during the winter 1919–20. The natives of these provinces are not well vaccinated, and in consequence the disease spread rapidly and the mortality was high. Effective steps were taken to prevent its spread north. A small outbreak occurred also in the Berber province, traced to a man from Omdurman where no cases were known.

An epidemic of influenza occurred in the Kassala province early in 1920, but the type was mild. Cerebro-spinal meningitis broke out in Western Mongolla with a heavy mortality. Diphtheria was more than usually prevalent in Khartoum and Atbara. Malaria was very prevalent owing to the heavy rains.

The Midwives' Training College at Omdurman is completed and work will be commenced there shortly. A site for a leper colony has been found up the Atbara, and it is hoped funds will be available for building there. The cost of administration has been considerably increased, as, apart from the increase of pay granted to all personnel, the price of materials shows little tendency to fall. Drugs, instruments, bedding, &c., are all at least double pre-war price. Such common drugs as quinine and Epsom salts have risen to four times their former price. Doctors have been difficult to obtain, and though the establishment of medical inspectors has been completed, it has not been found possible to fill the establishment of medical officers. The formation from trained native hospital attendants of a staff of assistant medical officers has proved of considerable value and helped to meet the deficiency of doctors.

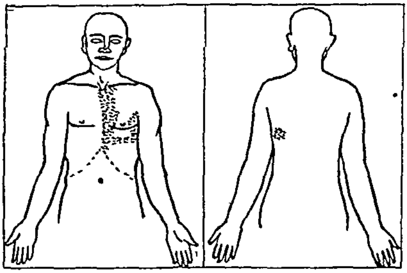
The recorded births in 1919–20 were 23,793 as against 23,033 in 1918–19, and the recorded deaths were 17,835, against 22,255. These figures, so far as they can be accepted as correct, are satisfactory, the births showing an increase of 760 and the deaths a decrease of 4420. 156,378 vaccinations were performed. Out-patient attendances in the civil and military hospital show a net increase of 8890 and in-patient of 1111.

Medical Examination of Labourers.

It has been considered necessary to enforce a more rigid examination of labourers from Upper Egypt before their entry into the Soudan. This is being carried out at Halfa and involves detention in the quarantine camp there for a period of three days; 100 to 150 men daily, or between 600 and 900 a week, are medically examined, shaved, bathed, disinfected, and treated with some vermifuge. The percentage up to date found infected with ankylostomiasis is

Action of the Scalenes.—Ordinarily the anterior scalene alone acts in inspiration, as can be easily demonstrated. In dyspnœa, when the upper thorax is markedly elevated, all the scalenes not only act forcibly in inspiration, but do not relax until the expiratory phase is half completed. In fact, in dyspnœa they work considerably over time. With the thorax becoming rigid the scalenes perform the whole work of elevation of the thoracic cage.

FIG. 1.

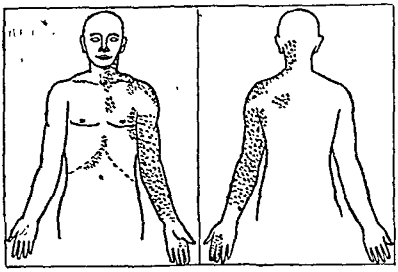


Left triangularis sterni: 14 cases.

Intercostal Muscles.—These muscles frequently contract in both phases of respiration. In the upper spaces the inspiratory contraction is certainly greater than the expiratory.

Triangularis Sterni.—This muscle arises from an inconstant area on the back of the sternum and xiphisternum and is inserted into a varying number of ribs, extending in some cases as high as the first or second rib, and fairly constantly into the third, fourth, fifth, and sixth. The lower fasciculus of this muscle extends horizontally outwards, being inserted into the fifth or sixth rib and cartilage. In such individuals as present a broad epigastric angle, the action of this muscle can be estimated by inserting the tip of the little finger between the xiphisternum and the costal margin. By this means it can be detected that this fasciculus is purely expiratory in those individuals in whom respiration is largely produced by thoracic elevation. The converse is true, it is inspiratory in those who adopt the lower thoracic abdominal type of breathing, and in the average individual it is active both in inspiration and expiration.

FIG. 2.

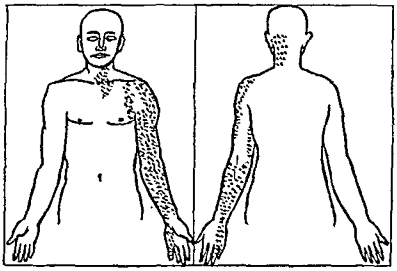


First left intercostal space: 13 cases.

Under various circumstances, these muscles tend to become tender to pressure. It is certain that they may be temporarily overworked under the circumstances mentioned above. When the strain is removed the tenderness disappears and they rapidly recover. Similar tenderness producing local and referred pains not infrequently arises as the result of spasm in cases of pleurisy or pneumonia, but lasts usually not more than 48–72 hours. In some instances, however (more especially where shortness of breath is present on exertion), pain is more persistent, and cases are met where comfort has been absent for many months. In such cases local tenderness and reference of pain are more continuous. Probably general asthenic and toxic conditions predispose in both acute and chronic forms. The important factor in the more persistent ache I believe to be the ossification of ribs and cartilages. This change hinders the rotation of the ribs on their own axis. As a result the thoracic cage is elevated en masse. The scalenes are called on for greater exertion.

When the triangularis sterni is tender and pressed on the patient it indicates that the pain is felt behind the sternum. In marked cases the area indicated in Fig. 1 extends the whole way up the sternum to the lower part of the neck in the middle line, and somewhat over the adjacent costal cartilages and generally to the homolateral side. It is frequently accompanied by a sensation which causes the subject to exclaim "It goes through to my back," "It stops my breathing," "Crushes my heart," or "It is *the* pain," phrases showing that the patient recognises it as previously experienced. It was affected in 19 cases.

FIG. 3.



Left anterior scalene: 19 cases.

AREAS OF PAIN.

An intelligent patient can distinguish that the stab occurs either during inspiration or expiration. The pain of the triangularis sterni evoked when the muscle contracts most forcibly during inspiration—i.e., in lower thoracic abdominal breathing—extends outwards along the fifth or sixth spaces of the same side into and beyond the axilla, and as high as the second rib. This is a common area for pains, in women especially, and is frequently regarded as hysterical. Pressure under the left breast in the fifth space will almost certainly affect the triangularis near its insertion to the rib or cartilage.

Fifth intercostal: These are not frequently affected. In the 9 cases recorded pain was referred to the anterior axillary area in five instances, and to the middle line in four.

Fourth intercostal: These are more frequently tender. Pain was referred to the shoulder in 1; anterior axillary area, 6; occipital, 1; mid-line (sternum), 2; inner arm, 1; outer arm, 2 (11 cases).

Third intercostal (11 cases): Shoulder, 2; anterior axillary, 4; occiput, 2; sternal, 0; inner arm, 1; outer arm, 2.

Second intercostal (13 cases): Shoulder, 2; anterior axillary, 4; scalp, 1; sternal, 5; inner arm, 3; outer arm, 2.

First intercostal (18 cases): Shoulder, 4; anterior axillary, 7; occiput, 1; sternal, 4; inner arm, 5; outer arm, 2. (Fig. 2.)

Post. scalene (11 cases): Shoulder, 6; anterior axillary line, 1; occiput, 4; inner arm, 2; outer arm, 2.

Mid. scalene (5 cases): Anterior axillary, 2; sternal, 2; inner arm, 2; outer arm, 2.

Ant. scalene (21 cases): This is the most prolific muscle in referred pains. Shoulder, 7; anterior axillary, 6; occiput, 1; sternal, 6; inner arm, 6; outer arm, 6. (Fig. 3.)

In the illustrations of these areas I have, as a rule, represented the left side only as being affected in order to avoid duplication. *The right side has been affected in a few cases.*

MILK—NOT FOR ANALYSIS.

ON Nov. 3rd a Brighton dairyman was fined £5 on each of two summonses: (1) for refusing to sell milk to an inspector, and (2) for obstructing the officer in the course of his duties. Rather than supply the inspector with a sample of milk for analysis defendant overturned his cart, and a churn full of milk ran down the gutter. The magistrates refused to believe that this was an accident. The dairyman successfully evaded inquiries from the bench about his alleged remark that the milk was sour and that he was "taking it up the side streets to get rid of it." The district where the inspector met defendant with the milk is the poorest in Brighton, and the result of an examination of its quality would have been of interest.

COLLAPSIBLE DOUCHING APPARATUS.

MANY patients who are taught to irrigate themselves complain of the difficulty of concealing the necessary apparatus, especially in taking it from their bedroom to the bathroom, without disclosing a bulky parcel. Dr. A. Allport has devised a collapsible vessel made of rubber which will fold up and go into the pocket, and which can be extended and made rigid by means of a vulcanite stay or prop. It is graduated inside up to two pints and is worked on the syphon principle, the syphonage being started by a rubber suction bulb. This bulb may be fitted to the Janet's nozzle, together with the rubber shield, and used as a hand syringe if required. The makers are Messrs. W. G. Holman, Beauchamp-place, Brompton-road, S.W. 3.

COLLECTING ANTIQUES.

THE narrative of a 25-years' search for antique furniture, prints, china, paintings, and other works of art cannot fail to find an appreciative public among those who themselves have made collections or who are about to start on this fascinating pursuit. Mr. Felix Gade, in a book entitled Collecting Antiques for Pleasure and Profit,[1] writes with infectious zest of seventeenth-century lacquer and marquetry, of twist-leg furniture and gate tables, Cromwellian chairs, and oak chests; deals briefly but adequately with Queen Anne furniture and the Chippendale, Hepplewhite, and Sheraton periods; and then digresses pleasantly on the miscellaneous extras—old clocks, decorative needlework, rugs, carpets, and engravings. He adds to much valuable advice some amusing gossip, and a list of prices recently paid for works of art in good condition concludes the volume.

LECLANCHÉ CELLS.

WE have received from Messrs. Siemens Bros. a set of catalogues containing illustrations and descriptions of various types of Leclanché cells. This firm has paid much heed to the construction of these cells, and many improvements have been effected in details of design. They have been constructed in many different sizes, both in the wet and dry form, and batteries can be obtained which will yield currents suitable for various purposes. The medical practitioner will be more interested in those which have been designed for the production of current for direct application to the body, as for ionic medication. Dry cells form an important source of current for those who require portable apparatus for the treatment mentioned, and they are extensively used. There is no reason why wet Leclanché cells should not be used by those who have no access to the direct main current. In the absence of a main supply, wet cells are preferable to dry cells when portability is not essential, and a battery of 40 could be permanently installed. If water is added occasionally to replace that lost by evaporation, and some sal ammoniac supplied from time to time, these cells will last for years. The zinc rod which slowly dissolves can be replaced, but this need be done only at long intervals. There is one special advantage which accompanies the use of cells for the production of current for direct application to the body. The current from cells is a true constant current, while that obtained from the direct current dynamo, which provides current on the main, is not absolutely constant, but slightly undulatory. The current from small dynamos is still more undulatory, and when a strong current has to be applied to the body, it is more readily tolerated if it is derived from cells. When the dynamo is used as a source of the current, the fine undulations are quickly perceived by the patient and cause disagreeable sensation when the current is much increased. Indeed, in a recent work on Medical Electricity, by Delherm and Laquerrière, the authors insist on the necessity of the use of the current from cells or accumulators for the treatment of neuralgia. They state that if the direct current from the main is used, the patient's tolerance will be overstepped before a current strong enough to procure relief can be applied. They ascribe failure to obtain relief to the use of currents which are insufficiently strong, and they show that a current of the requisite intensity cannot be tolerated if it is obtained from a dynamo. In the early days of the Electrical Department at St. Bartholomew's Hospital, before a main supply was available, the constant current was derived from wet Leclanché cells. There were three batteries, each containing 50 cells.

Messrs. Siemens's catalogues will be interesting to the practitioner of electro-therapeutics. They are well prepared and copiously illustrated.

A DEFINITION OF FINE CHEMICAL.

THE answer to the question, What is a "Fine Chemical?" is given by Mr. C. A. Hill, B.Sc., F.I.C., in a paper appearing in the *Journal of the Society of Chemical Industry* for Nov. 30th. The term used to be employed loosely, sometimes to signify synthetic organic substances, sometimes analytical reagents or research chemicals, and frequently in a sense more vague than either of these. The Safeguarding of Industries Act has raised the necessity of deciding definitely whether a given chemical product is or is not a fine chemical. In deciding the point, all the attributes of chemicals have to be considered: scale of manufacture; conditions of manufacture; skilled labour; highly skilled supervision; rarity; high cost; high grade of purity; and freedom from impurities. Each of these ideas contributes something to a general understanding of what fine chemicals are. But the real crux is the idea that the chemical is to be put to some specific use and for that purpose must conform to some definite standard of purity. The shortest description of a fine chemical which is in any way adequate is that it is a chemical, not produced as a "heavy" chemical, which is of specified purity for a specific purpose.

A DISCLAIMER.

To the Editor of THE LANCET.

SIR,—It has just been brought to my notice that my name was mentioned in a Sunday paper last week in regard to the case of a boy who had been seen by Pastor Jeffreys at Notting Hill. I need hardly state that I was quite ignorant of the fact that my name was to be published and I never gave any permission for it to be used in any way. I should be much obliged if you could kindly find room to insert this letter in your journal.

I am, Sir, yours faithfully,
Wimpole-street, W., Dec. 3rd, 1921. GEORGE N. BIGGS.

SUCCESSFUL QUACKERY.

To the Editor of THE LANCET.

SIR,—When I was in Australia some 30 years ago a certain notorious "herbalist" in Sydney, N.S.W., was prosecuted for practising without a diploma and for obtaining money by false pretences. He had an enormous practice and the medical faculty were, very naturally, indignant about it. But when summoned, the man was able to produce incontrovertible evidence that he was a duly qualified medical man. The account he gave of himself was as follows:—

"When I started practice as a doctor, I hardly ever got a patient, but I saw several 'herbalists' and unqualified men doing an enormous and lucrative business. So, in desperation, I determined to follow their methods, with what success you know. The ignorant public here will pay handsomely for quackery and imposture, but are niggardly towards genuine medical work."

I fear that Sydney is by no means the only place where this is so, and until our more ignorant portion of the population is elevated from their present condition of stupidity there will always be an opening for the humbug, the impostor, and the quack.—I am, Sir, yours faithfully,

F. A. PARKER, M.A. Cantab.
Carnforth, Lancs, Dec. 2nd, 1921.

part of the chest and extended into either arm. He was a big man. The Wassermann was negative, heart and lungs were normal, there was no albumin. Three pieces of strapping were applied round the chest at the level of the base of the sternum with intense relief; he reported in the following week that he had been at work the whole time. The pain had pulled him up three times but there had been more ease than for two or three years. On this occasion, on taking off the strapping, an anginal attack developed. He stood still, it could not be observed that he was breathing, he could not speak and had intense pain located behind the sternum. He began to sweat and his face became white. He would not move to sit on a chair which was brought; his face expressed extreme pain. The attack was relieved by amyl nitrite. An attempt was made to improve upon the strapping, but, owing to a piece of metal introduced causing cutaneous irritation, the apparatus could not be worn. The following week he reported that the pains had been severe; he had had bad nights, but no acute attacks. On this occasion (June 11th, 1919) he was re-strapped and on July 2nd, he reported again and no local pain was present. Eventually he was fitted up with a mechanical arrangement; he reported again a year later and was still wearing it, but now had a complaint of pain occurring after food with some vomiting and flatus. There had only been a few severe anginal attacks following exertion. The continuous ache had disappeared, the triangularis was hardly tender at all. A bismuth meal showed no evidence of obstruction and his symptoms of dyspepsia were relieved following the extraction of several teeth which showed pyorrhœa.

An Explanation of the Sequence of Events in Angina.

Important to my thesis is the phenomenon observed when pressure is made on the hypersensitive triangularis sterni and sometimes on an intercostal or scalene should they be tender. The chest is elevated and held there with a diminished respiratory excursion. Such elevation is carried on against the action of gravity and is produced by muscular action of the scalenes. The scalenes do not relax to the full, otherwise the chest would resume the original expiratory posture and the tracing would fall to the level upon which it stood, prior and subsequent to the pressure on the triangularis. The triangularis does contract in expiration and it is the scalenes which become tonically contracted and oppose the full action of that muscle. It is thus not difficult to conceive an explanation for the sequence of events usually found in an attack of angina. The area becoming sensitive from the stimulation of the triangularis, will account for the preliminary warnings of pain in the region of the sternum. If neglected, an increased thoracic elevation ensues, resulting in a tonic condition or spasm of the inspiratory muscles of the upper portion of the chest, producing a pain referred to the shoulder, axilla, or arm; the muscle exhibiting tone and not relaxing in expiration will produce these areas, which I believe to be associated with increased action in expiration, to the sternum or anterior triangle.

Referred Pain in Various Diseases.

In collecting the details for this communication I find that referred areas of pain from these accessory muscles of respiration have occurred in various diseases. These observations are drawn from a series of over 50 cases, of which I think seven would be included as angina by a strict definition and a further 10 by those inclining to a wider classification. I have given short details of three cases in the first class of seven. The class including 10 cases consisted chiefly of individuals who were pulled up by pain in the chest on exertion. In most of these, attacks of pain have occurred in the characteristic anginal areas, and they had believed they were dying. Nine cases are included in a separate group, where similar symptoms were noted but where a valvular lesion was present in addition. In a fourth group of 10 cases pleurisy or pleuro-pneumonia was present in eight, and intrathoracic neoplasm in two. Asthma, emphysema, and chronic bronchitis afford another group of five. Eight cases of an anomalous type constitute a further group (and seven cases were selected from patients whose primary symptoms indicated pain arising from conditions other than respiratory stress—e.g., occupation neurosis, &c.). Such different types suggest that we are dealing with a group in which similar pains of varying severity occur. Throughout this group it seems difficult to exclude the element of respiratory stress. In some of the cases it is the essential phenomenon.

Summary.

In conclusion I sumbit that—

(1) Over fatigued muscles give rise to referred pain in distant areas.

(2) The upper thoracic respiratory mechanism is excessively active under the same conditions in which attacks of angina pectoris usually occur, and stress of this nature affords a better explanation for nocturnal attacks than does cardiac strain.

(3) The respiratory muscles of this region, when hypersensitive, are the last structures in the segment to lose local tenderness and the faculty of producing referred pains by pressure.

(4) When these muscles are hypersensitive and subjected to pressure the areas to which pain is referred correspond to those similarly affected in angina pectoris, and are frequently recognised.

(5) I have demonstrated a phenomenon which offers an explanation for the warning and sequence of spread of pain in angina pectoris. This is dependent upon irritation of one of the expiratory muscles involved, and results in marked thoracic elevation.

(6) Treatment by alleviating the stress of these muscles has frequently—not always—been effective in relieving the pain *without* other treatment.

(7) Two attacks of angina pectoris have been observed as the result of irritation of respiratory muscles.

(8) I submit that the phenomena generally which accompany an attack of angina pectoris can equally well be explained on a respiratory hypothesis as on one of vascular origin.

(9) I would further point out that the age incidence of angina pectoris corresponds with that of ossification of the ribs and cartilages—a source of increased difficulty in respiration.

SPASMODIC RESPIRATORY AFFECTIONS.[1]

By Sir JAMES PURVES STEWART, K.C.M.G.,
M.D. Edin., F.R.C.P. Lond.,
SENIOR PHYSICIAN TO THE WESTMINSTER HOSPITAL.

SPASMODIC respiratory affections may be due to disease either of the vegetative or of the cerebrospinal nervous system. With regard to the vegetative nervous system I mention in passing the important spasmodic respiratory affection known as asthma, whose phenomena of laboured breathing consist essentially in spasm of the non-striped bronchial muscles, innervated as we now know by the dorsal motor nucleus of the vagus. In asthma the bronchial nerve centres react with abnormal violence to various blood-borne irritants, whether these be foreign proteins or bacterial toxins, also to peripheral irritants, nasal or otherwise, or even to psychical stimuli. The result is the asthmatic paroxysm, whose features are so familiar that I need not weary you by recapitulating them.

The "Hic" and the "Whoop."

Coughing, yawning, sneezing, and hiccup are all of them reflex phenomena which may be induced in healthy individuals by appropriate stimuli. Of these, hiccup calls for special mention. Hiccup is a spasmodic myoclonic contraction of the diaphragm, occurring so suddenly that the glottis is momentarily closed by suction, producing the characteristic inspiratory noise or "hic." In slight cases of hiccup the affair is transient and produces only trivial discomfort. Sometimes, however, it may become so severe and prolonged as to induce profound and even deflation of the lower lobes of the lung, not infrequently seen in cases compelled to complete recumbency following operations and otherwise.

---

[1] Being the concluding portion of the Purvis Oration on Respiratory Phenomena in Nervous Disease, delivered before the West Kent Medico-Chirurgical Society on Dec. 9th, 1921.

In these conditions, and indeed in dyspnœa generally, stress falls in particular upon those muscles which are active when inspiration consists largely in elevation of the thorax.

STRESS OF SKELETAL MUSCLES.

Quite apart from respiratory muscles, skeletal muscles become hypersensitive when over-stressed or chronically fatigued, and further, pain is referred over a wide area. In three cases of occupation-neurosis resulting from over-use of the arm or malposition in the use of the hand, I have found the trapezius muscle to be tender to pressure. The pain arising from this muscle is appreciated either at the back of the occiput as high as the occipital ridge, as far back as the middle line and as far forward as the mastoid process, or in addition as extending upwards in front of the ear, through a narrow area over the cheek as high as the zygoma. Here an area a little smaller than a hemi-section of a tennis-ball is appreciated as being the seat of "neuralgia." In two instances this same area became considerably reddened as the result of vascular dilatation. The pain was recognised as having been appreciated before and was induced by the use of the arm. In two cases the muscles lying between the metacarpal bones of the thumb and index fingers, probably part of the adductor pollicis, were hypersensitive, the pain being referred over an area triangular in shape, its base limited below by the level of the wrist-joint both anteriorly and posteriorly, and ascending to an apex over the middle part of the forearm on its radial border. In cases of acute flat-foot pain may also be produced in the leg. In one instance such a pain was felt over an oval area on the outer part of the thigh extending from a point just above the external condyle of the femur as far as the great trochanter. In other cases the pain has been appreciated either in the inner or outer side of the leg between the knee and the ankle and in well-defined areas. The pains in these cases have been recognised by the individuals as occurring previously. It will be noticed that I am not claiming any specific property on behalf of the respiratory muscles.

The method I have adopted in testing these muscles is first to pick up the skin between the finger and thumb and apply gentle pressure, secondly to take hold of the muscle, or to locate the muscle with the finger, and apply similar pressure; if pain is absent on the first occasion and present on the second I conclude it is due to the muscle itself, though it is not possible definitely to exclude the subjacent tissue. That the muscle is the cause of the pain is most probable when it is remembered that putting that muscle into action by the individual produces similar pain to that which follows pressure.

On producing the pain by pressure, the subject generally indicates the area of pain with a wide movement of one hand. He is then asked to indicate it more exactly, and will usually show an area less than that originally indicated. Various points in the neighbourhood of the margin of the area are then indicated and the question asked, "Do you feel it here?" and by this means the area in which the pain is appreciated can be more or less accurately differentiated. In some cases the method employed by Head has been adopted for testing different areas, and the maximum points of pain are found to correspond to those which he has published. In such cases the pain has usually been of great intensity. Patients cannot always be examined during such paroxysms, nor do they appreciate prolonged handling of a muscle which produces pain of such severity.

DEGREES OF PAIN.

In respect of degrees of pain felt in these muscles, for all practical purposes, the following categories may be differentiated: (1) All structures in the segments are locally tender and produce referred pain; (2) the skin is not tender, but the remaining structures, both bone and muscle, are hypersensitive and refer pain; (3) the skin and bone are not tender to pressure—the muscle is tender and produces the referred pain; (4) the muscle alone is locally tender—i.e., "the pain is under your finger," and either produces no referred pain or such an area is diminished in extent.

The muscle which has been tender either with referred or local pain will lose such sensitiveness in time and pain will not be elicited on pressure such as has been employed previously. It may disappear in a few hours, occasionally in a few minutes, and commonly in less than 12 hours. On the other hand, the sensitiveness may remain for days or even weeks. In the case of a lady who had suffered pain for two years, in whom the trapezius was put at rest by means of a sling, the muscle remained locally tender for three weeks but was not tender at the end of six weeks. The hypersensitiveness re-developed in an hour when the sling was left off and the muscle was again brought into action.

AREAS TO WHICH PAIN IS REFERRED BY MUSCLES ACTIVE IN UPPER THORACIC RESPIRATION.

Returning to the respiratory muscles, I find the following areas, generally on the left side, occasionally on the right, frequently indicated as being the site of pain when pressure is applied to a tender muscle:—

(1) The inner arm, upper and lower, extending over the areas allocated to the first, second, and third dorsal segments.

(2) Other parts of the arm or hand not always corresponding to a segment. The thumb has in my series not been affected. To distinguish from the first area this may be called the outer-arm area.

(3) Anterior axillary area extending from a line somewhat external to the nipple as far as the free margin of the anterior axillary fold. Above, it extends to the level of the first rib, sometimes higher, to a point over the coracoid process. Below, less definitely to the level of the fifth or sixth rib.

(4) An area in the shape of the brim of a cocked hat placed over the apex of the shoulder.

(5) An area extending from the occipital ridge with an indefinite lower border well down the neck. Bounded by the middle line internally its anterior limit is a line dropped from the mastoid process towards the acromion.

(6) A central "sternal" area limited to the homolateral part of the sternum and adjacent costal cartilages. It may extend upwards to include the anterior triangle of the neck and grip the throat.

The extent of these areas varies at different times and in the same or different individuals. Usually, the upper border is more sharply defined than the lower. Other areas are occasionally and irregularly the site of the pain produced.

Time does not permit me to enter fully into the muscular mechanism of respiration. After studying this subject for several years I must confess it is most complicated. It may, however, be safely stated that whenever the influence of effort enters into respiration—be it from exertion, emotion, pain, cardiac defects, or what not—there is an increase in the depth of inspiration, in which elevation of the thorax plays an excessive part. As I mentioned before, the same may happen when the supine posture is adopted.

The muscles principally concerned in this are the scalenes and upper intercostals in inspiration, and the triangularis sterni in expiration. The three scalene muscles which rise from the transverse processes, the anticus and medius being inserted into the first rib, and the posticus into the second rib, form—together with the intercostal muscles of the first space—the motor mechanism of a unit of expansion for the upper part of the thorax. This consists in the manubrium sterni, the vertebræ, the first two ribs, and Sibson's fascia. The third and fourth ribs are much less firmly attached to the sternum than the first and second. With the intercostal muscles attached to them they provide a link between the upper and lower part of the thorax.

jerky movements of the arms; another individual gives an occasional little nervous cough or grunt, and so on. Then again, one variety of stammering, in which the patient sticks in the middle of a vowel (less common than the type where he sticks over a consonant) is simply a respiratory tic affecting the muscles of the false vocal cords. Examples of tics or habit-spasms of this sort might easily be multiplied, and many of you can recall for yourselves friends or patients who perform peculiar respiratory actions of this sort. A tic or habit-spasm, it should be remembered, is a psychomotor affair of cortical origin, consisting in the frequent explosive repetition of the same motor act. It never interferes with voluntary movements. Sometimes the tic takes place automatically and without the patient's conscious attention; in more severe cases the tic absorbs the patient's attention during its performance, and is accompanied by a feeling of irresistible compulsion. The greater the psychical abnormality the more violent does the tic tend to be.

THE

NOSE, THROAT, AND EAR REQUIREMENTS OF AIRMEN.

PROBLEMS PRESENTED BY THE INTERNATIONAL MEDICAL REQUIREMENTS FOR AIR NAVIGATION, WITH SPECIAL REFERENCE TO THE NOSE, THROAT, AND EAR.

BY DAVID RANKEN, M.S. LOND., B.S. DURH., F.R.C.S. ENG.,
SQUADRON LEADER AND NOSE, THROAT, AND EAR SPECIALIST, R.A.F. MEDICAL SERVICE.

THAT the airman should be medically fit is a dictum that none can deny. It stands to reason that anyone subject to rapid changes of atmospheric pressure and with such physical responsibilities as are demanded of a pilot should be organically sound, especially in regard to the nose, throat, and ear. All aviation medical boards, therefore, have laid down standards which, in the early days—when indeed there was often little or no medical examination of flying personnel—were mostly arbitrary, but which became modified from time to time as knowledge was acquired of the physiological attributes essential for successful flying.

The object of this paper is to discuss such physiological attributes in regard to the nose, throat, and ear, and to draw attention to the process by which these standards are being confirmed or refuted. With more than four years' experience *in the examination of* candidates, I know of many instances where the question of acceptance or rejection of an individual has produced sound arguments on both sides; in consequence, it has seemed to me of interest and value to consider some of these cases, *more especially in the* light of the international medical requirements for *civilian pilots*. It is *necessary to pass in review* the experiences upon which such requirements were undoubtedly founded.

The Aviation Candidates Medical Board of the Royal Air Force insists that candidates with no previous experience of flying shall have hearing in either ear equivalent to a forced whisper at a distance of 20 ft.; perforations of the drum, chronic suppurative otitis media, and a radical mastoid operation, successful or otherwise, are causes for rejection. These are excellent safeguards: a fair number of pilots who—either inadvertently or before the Aviation Candidates Medical Board was established—were instructed in flying, were then found to have trouble in the air, and have since been invalided out for one or other of the reasons cited above. They frequently suffered *from dizziness or headaches, sickness or exacerbations* of chronic suppurative otitis media, pain or ringing in the ears, and there was always the chance of labyrinthine involvement through a necrosed inner wall of the middle ear. The experience of the medical *services of other countries has been similar. It is* better, therefore, not to take initially the risk of these complications, but where no trouble has arisen over a period of years it becomes a matter for careful thought as to what decision to make.

The International Medical Requirements.

As stated above, many of the rules laid down by Aviation Candidates Medical Boards were in the first place empirical, but the international medical requirements differ in being succinct, and in virtue of what they definitely contain, or perhaps purposely omit, are capable of wide interpretation according to the views prevailing in any particular country. The following are those laid down for the nose, throat, and ear:—

> "*Ear Examination.*—The middle ear must be healthy. The aeronaut must possess a degree of auditory acuity compatible with the efficient performance of his duties.
>
> *Vestibular Mechanism.*—Must be intact and neither unduly hypersensitive nor hyposensitive.
>
> *Nose and Throat Examination.*—The aeronaut must possess free nasal entry on either side and not suffer from serious acute or chronic affections of the upper respiratory tract.
>
> Each contracting State for the present is to fix its own method of examination and no aeronaut who has given proof of his flying ability shall, so long as he retains such ability, be necessarily disqualified because he fails to fulfil all these requirements."

I wish to call particular attention to this latter clause. Let us now consider these requirements seriatim.

A Healthy Middle Ear.

It was probably felt that external ear and meatal conditions could be left to the discretion of the examiner, but that there could be no dispute as to rejection where pathology is present in the middle ear. I have accordingly taken the records of 450 civilian, or rather would-be civilian, pilots for passengers or goods examined by myself since the armistice; these are the findings in cases where the middle ear was not healthy:—

1. L. Has *flown* 600 hours during the war. Is now deaf in left ear; a dry perforation on that side. Possible initial date of ear trouble, May, 1918. Became troubled *with giddiness in the air in March and April,* 1919. This candidate would, no doubt, be unsafe as a civilian pilot and he was accordingly rejected.
2. C. *1050 hours previous flying. A small posterior* inferior perforation of left drum, and left ear has discharged off and on during last 12 years—i.e., trouble commenced long before he learnt to fly. *Although middle ear was not* healthy, and never likely to be so without operation, absence of symptoms with a good flying record was satisfactory, and he was accordingly accepted.
3. M. 500 hours previous flying. Chronic suppurative otitis media both ears, date of origin unknown. Hearing right ear fair but only 1 ft. for a forced whisper in left ear. Candidate deferred for aural treatment, never previously having had any, but failed to present himself for re-examination.
4. K. 300 hours previous flying. Right ear has discharged off and on since childhood; forced whisper heard at a distance of only 4 ft. on that side; large dry perforation in right tympanic membrane. A view similar to that in Case 2 was taken, and he was accepted.
5. B. Has flown over 2000 hours; airman by profession. Ears have run off and on since childhood; hearing good in either ear, right drum scarred; a large posterior inferior perforation in the left drum. Assessment similar to that made in Case 2.
6. S. Number of hours flown about 1250; a discharge from left ear off and on since age of 12. Hearing on both sides good, but right drum opaque; an anterior perforation *of left drum. Candidate accepted.*
7. T. Has flown more than 1000 hours. In 1911 left ear discharged, and has run off and on since. Hearing good *in either ear, but a posterior superior scar in left drum.* Candidate accepted.

Bearing in mind the frequency of breakdown of pilots suffering from a like condition, the outstanding feature of the above and subsequent cases is, I think, *adequate* illustration of the fact that in certain people the bodily mechanism can, for a time at any rate, rise superior to serious physical defects. A consideration of the above cases shows, moreover, the wisdom of a *saving clause as to previous flying ability. It was felt that five of the seven candidates described*

These pains are not always constant for the same muscle; for instance, the anterior scalene may on one occasion refer pain to the inner side of the arm, and on a second to the shoulder, or the posterior scalene to the shoulder on one occasion and to the occiput on another. Further, in a given individual several muscles may be tender and refer pain at a given interview. The interpretation of the pain which he gives tends to vary, as has been indicated above. It is further noticeable that in the same patient on successive days different muscles may be tender; this is particularly noticeable with the intercostal spaces. For instance, on one occasion the fourth space may be tender and the higher space unaffected, whereas on a different occasion the fourth may not refer pain and be locally tender, whereas one of the higher spaces, such as the first or second, may refer pain.

There is strong evidence to show that the triangularis sterni refers pain to different areas when fatigued in expiration or in inspiration. There is also some support of a similar differentiation in the case of the anterior scalene. Possibly the spinal cord contains groups of cells in different areas which control the muscular actions for the two phases of respiration.

Thus all these muscles which become tender give referred pain in various areas outside themselves, but they share these areas in common and the composite area diagrams of any of these muscles produce a diagram which would be satisfactory for some cases of angina pectoris. These areas are: (1) Inner arm —corresponding to Head's areas 1, 2, 3 dorsal; (2) outer arm—rest of arm; thumb never seen affected; (3) anterior axillary area; (4) shoulder; (5) occiput; (6) sternal.

Two points appear to me to be important—namely: (1) If we add any intercostal or scalene areas together we get a composite area of referred pain which corresponds with that of angina pectoris; (2) that it is common for the patient to recognise the pain produced by muscle pressure as having been experienced before, as being, in fact, his particular breast pang or angina.

A CASE ILLUSTRATING RELIEF BY PRESSURE.

F. S., aged 53, was admitted to the out-patient department with extreme pain in the left arm. It commenced suddenly three weeks ago while walking, has been remittent in character since then, and is brought on by any exertion, especially by use of the left arm. The pains may occur any time during the day, but are most frequent at night. By occupation he is a labourer in regular work. He walked into the out-patient room supporting the left arm with the right, holding it tightly against the chest. His gait was slow and careful, pausing occasionally in between the paces. He sat down carefully, kept quite still, would not move his head on account of increasing the pain, and stated that his most comfortable position was on the back slightly over to the left. Movement of the elbow caused pain in that joint. A slight spasm was seen in the out-patient room during which the face went ashy grey and his eyes were filled with tears. He stood perfectly motionless. Strapping applied below the nipples relieved, but did not completely stop the paroxysm. He was admitted forthwith. The Wassermann reaction was positive. While in hospital he had many attacks and his muscle tendernesses were tested on several occasions. On one occasion, pressure on the anterior scalene precipitated a typical attack, which was relieved to some extent by amyl nitrite. During these attacks the pulse-rate was not altered. If the strapping was left off, injections of morphia had to be given. Spring tapes relieved acute attacks, but did not entirely prevent minor attacks. In particular the gnawing pain in the upper arm tended to continue, without acute exacerbations to prevent him sleeping. He was fitted out with an apparatus on the lines indicated and left the hospital on Dec. 23rd. He has been seen at out-patients' since that date. He declines to give up his apparatus. No acute attacks have occurred and the aches are now passing away. The muscle tenderness has also ceased, and he is now anxious to resume work.

IMPORTANCE AND LIMITATION OF RELIEF BY PRESSURE.

This fact of relief by pressure appears to me of critical importance. Relief to the triangularis sterni may be attained by lateral pressure as by the hands by means of strapping, and in many cases I have carried this out with immediate relief of the pain. A piece of strapping carried round the chest at the level of the lower end of the sternum is all that is necessary. It prevents the full inspiratory action of this part and further diminishes the action of the scalenes by inducing a compensatory action of the lower thoracic respiratory mechanism. Strapping tends to stretch, is unpleasant for the patient, and produces a feeling of uneasiness owing to the inability to take a deep breath. I now employ a broad piece of webbing in which is inserted a spring. This does away with the alarm produced by complete constriction, and is a more desirable method of relief because it assists and does not replace the action of the muscle. It is effective in this condition, and frequently also relieves similar referred pains and many pains in cases where the muscles are locally tender to pressure which arise in the course of pneumonia and pleurisy.

This method of lateral thoracic pressure has its limitations. Where the ribs and cartilages are markedly ossified it may be quite impossible to produce any effect by this means, and where the respiratory apparatus, especially the lower thoracic abdominal portion, is under ordinary circumstances working at its maximum, the individual cannot tolerate any restriction whatever and his instinct will teach him that he must bear the pain rather than make more numerous respiratory efforts. The true vicious circle is therefore established. Lateral pressure produces its effect by promoting lower thoracic abdominal respiration at the expense and to the relief of the upper thoracic expansion. The characteristic attitude, if such there be, of angina pectoris is one in which the left arm is held tightly into the side and it is assumed that this posture is adopted to relieve the pain referred to the elbow. In such a case if pressure is brought to bear upon the inner side of the arm it does not relieve the referred pain. A different explanation may be offered—namely, that it is the effort of the individual, unconscious of the reason, to constrict the chest laterally, and this he can best do by folding the arms tightly across the chest. Imitation of this mechanism does, within limitations, relieve the pains and the attack very rapidly, and it is a most striking demonstration to watch the gradual disappearance of the pinched expression and agonised face which follows the gradual realisation that these pains have disappeared.

TWO OTHER ILLUSTRATIVE CASES.

F. S. J., aged 49, was brought to King's College Hospital by the police in an attack of angina. He was walking up Denmark Hill when he suddenly felt choking pains in the neck, left arm, and chest. He was in King's College Hospital in 1913 with severe anginal pains, intermittent in type and of a similar character to the present. In some of these attacks he thought he was dying. He was a sailor, but denied syphilis. His Wassermann reaction was not tested in 1913. At that time there was no evidence of organic disease. In the interim from 1913 there had been no attacks. He was seen in casualty, leaning back against a couch at an angle of about 80°, hardly breathing at all. The heart was quite steady but a loud systolic murmur was audible all over the præcordium. He had been there about half an hour; pain had ceased in the left arm but was still present in the left side of the throat and the upper sternum, radiating up and down. The face was not pale. The pain in the throat was described as gripping in character. Pressure on the first intercostal space on the left side gave no result; on the second and third spaces pain went to the left side of the neck in the region of the trachea and was identified as *the* pain. The fourth and fifth spaces referred to the axilla; the left triangularis sterni was very painful but did not radiate; the scalenes were not tested. Lateral thoracic pressure was stated to give relief, and he was accordingly strapped tightly below the nipples. This gave immediate relief, and three hours later all pains and soreness had disappeared and patient walked out wearing the strapping.

G. W., aged 46, formerly in the army, complained that for three years he had had an ache in the region of the xiphisternum, constant in nature, but increased by the use of the right arm, and when walking. He could walk three and half miles an hour, but this aggravated the pain and he had at intervals to sit down and rest. The pain diminished in the evening when sitting down, but woke him up in bed. During attacks he had to stand quite still; he sweated. On several occasions had thought he was dying, and on three occasions had fainted. In severe attacks pain was felt in the upper in recommending operation; some had already had operative interference with little amelioration as regards their mouth-breathing, and in some no vestige of a possible cause could be found and the condition was evidently a bad habit, and also, it must be said, not a very marked one.

Mouth-breathing per se is presumably a disability because of the frequently associated parched buccal and pharyngeal mucous membrane, spongy gums, or excitation produced by currents of air on carious or ill-stopped teeth or unhealthy tonsils. These symptoms are much more pronounced in some individuals than in others, and quite a number of mouth-breathers neither have nor complain of any discomfort. One must remember also that mouth-breathing itself is only a symptom, sometimes, but by no means always, associated with other physical or skeletal conditions such as deformed chest or highly arched palate. Again, nearly all pilots above a height of 12,000 ft. begin to breathe through their mouths in order to obtain sufficient oxygen from the rarefied atmosphere. The conclusion to be drawn, therefore, is that there are quite a number of pilots in whom mouth-breathing constitutes apparently no disability at all and that the assessment of any symptoms due to it is the important point.

Deviated Septum.

There is a small but distinct group of cases among these 450 experienced airmen in which nasal examination seemed to leave one no alternative but to say that submucous resection should be performed irrespective of the candidate's history of symptoms as given by himself. In this connexion one must remember that there is a marked tendency on the part of examinees to pooh-pooh any discovered apparent disability as having given rise to no, or at any rate, to only slight, trouble in the past. It must be remembered, on the other hand, however, while giving due weight to such a history, that symptoms apparently trifling in importance on the ground tend to become considerably aggravated in the air. Deviated septum, traumatic in origin, is of fairly frequent occurrence among experienced pilots, sometimes because of their sporting instincts in the way of boxing or the rougher games, but more so because of their liability to crashes with trauma about the face and head. In this class I must place six airmen out of the total number seen, not only because examination at once suggested the need for correction, but more so because of the concomitant symptoms. Frequent colds in the head with mouth-breathing were usual symptoms, obstruction in one or the other nasal passage was practically always present, while two were subject to attacks of hay fever. In spite of these signs and symptoms, however—i.e., acute and chronic affections of the upper respiratory tract and absence of free nasal air-entry on one or the other side—three of these airmen had successfully flown over 1000 hours, and the remaining three 150, 400, and 600 hours respectively. There can be little doubt that submucous resection would add materially to their comfort and well-being, and indirectly therefore to the longevity of their flying life.

Enlarged or Unhealthy Tonsils and Adenoids.

Ten airmen were found in whom signs and symptoms, such as marked hypertrophy, frequent sore-throats or attacks of quinsy, enlarged glands in the neck, and in the case of adenoids repeated colds and occasional attacks of Eustachian tube obstruction, left no doubt that operation would be an advantage. A large number of others with unhealthy tonsils was seen, who, on their own statement, had never had any trouble. These ten airmen, in spite of their symptoms, had flown periods ranging from 140 to 2700 hours. In this connexion I mention a well-known stunt pilot and instructor who, besides having a tendency to mouth-breathing with distinctly unhealthy tonsil remnants present, had a history of occasional migraine attacks, and also possessed visual defects. This pilot had flown 1550 hours, had been up to 23,000 ft. with no discomfort and without oxygen, and apart from a gunshot wound in the left leg in 1915 had never suffered from any disability!

Miscellaneous.

In this group I have placed four airmen. Two suffered from hay fever every year without any flying trouble. Both had flown successfully about 1500 hours. A third was subject to frequent colds and evidently had a very susceptible mucous membrane: when seen, the whole of the upper respiratory tract was in a condition of acute catarrh without any apparent clinical evidence of the cause. In spite of this he had flown 900 hours successfully. A fourth suffered from atrophic rhinitis probably due to too extensive turbinal operation in civil life, but had, nevertheless, flown 150 hours without discomfort or mishap.

Conclusion.

I have considered the above groups of cases because, although various aural or upper respiratory tract potential disabilities were present, the flying efficiency of the airmen concerned has been proved over and over again; I feel, however, as stated above, that it would be both wrong and misleading to quote such cases without again emphasising the point that in my opinion these airmen were successful *in spite of* their defects, and I cannot doubt that their standard of excellence would have been higher had they conformed to the normal. What really does matter, and probably happens in all such cases, is that a power of compensation exists and minimises any potentially troublesome defects. The same remarks might be made with regard to refractive errors in cases of maimed or partially disabled pilots and with respect to other physical conditions diverging from the normal. Such emphasis is perhaps necessary, as medical boards in all parts of the world have laid down stringent standards for untrained would-be aviators; tempered with discretion and discrimination, however, on the part of medical examiners there can be no doubt that this is, and has been, the right and wisest course to pursue.

Should any relaxation of medical standards be made when the demand for pilots exceeds the supply in the case, say, of another great war? If so, in what direction should this relaxation take place? Writing with respect to the nose, throat, and ear it is apparent that apart from a number of candidates who might be temporarily deferred for operative treatment, the debatable cases would be men with chronic suppurative otitis media with or without hearing defects, who were in other respects perfectly healthy. In a recent paper of mine entitled "The Incidence of Nose, Throat and Ear Disease among Aviation Candidates,"[6] I showed that only about 3·6 per cent. of the young men presenting themselves as aviation candidates suffer from aural disease, so that the number of such cases would be small; were it necessary to consider the question of admitting some of these candidates, and, in my opinion, this would only be justified under very extreme conditions, it seems that the presence or absence of symptoms or exacerbations of disease over a preceding lengthy period of years should play an important part in the adjudication; other things being equal, however, it would appear incontrovertible that a candidate sound and healthy in all respects is more likely to be useful and successful over a period of years than one with any physical defects, however unimportant the latter may seem to be at the time of examination.

fatal exhaustion. The reflex phenomenon of hiccup is sometimes excited by transient gastric or other abdominal irritation. It may also be due to disease of the peritoneum in the region of the diaphragm, the phrenic nerve being sensory as well as motor in function. Other cases of hiccup are due to central disease of the respiratory centres in the medulla. Thus, for example, it may be produced by the toxin of epidemic encephalitis. In encephalitic hiccup the myoclonic spasms may implicate not only the diaphragm and the constrictors of the glottis, but may even extend to the muscles of the abdominal wall and trunk. Hiccup of this encephalitic type may continue for days at a time, at the rate of 12 to 15 hiccups per minute. Most cases clear up in three or four days, but others go on for weeks. Hiccup may also occur as a terminal symptom in tumours of the posterior fossa of the skull. Lastly, we sometimes meet with cases of hysterical hiccup. These are recognised by their history and concomitant phenomena, and the symptom promptly subsides under appropriate suggestive treatment.

Before dismissing the subject of cough we ought to recall whooping-cough or pertussis, an infective disease causing irritation of the coughing centres in the medulla, with its initial and terminal stages of catarrh and its paroxysms of rapidly succeeding expiratory coughs, followed by a single long-drawn inspiratory laryngeal "whoop." These paroxysms of alternate coughs and whoop follow one another in succession until the attack culminates either in temporary apnœa with cyanosis, or in vomiting.

Laryngismus, Tetanus, Rabies.

Laryngismus stridulus, especially occurring in rickety children, consists in laryngeal inspiratory stridor and is often associated with tetany or painful tonic spasms in the hands and feet. Laryngismus itself may be regarded as a tetany of the adductor muscles of the larynx.

In the classical accounts of tetanus the respiratory muscles are described as becoming implicated in the general muscular spasm, so that during a severe tetanic paroxysm not only is there opisthotonos but also tonic spasm of the respiratory and laryngeal muscles, causing asphyxia which may be fatal. I had considerable personal experience of tetanus during the Gallipoli campaign and had the opportunity of watching a number of severe cases of tetanus. Seven of my cases were fatal, but in none of them did death happen to be due to respiratory spasm or to asphyxia; what the patient died of was progressive cardiac feebleness, sometimes several days after the tetanic spasms had subsided completely.

Personally, I have never seen a case of rabies, but the symptoms are described as being of two varieties, sometimes a spasm of the inspiratory muscles, as well as of the pharynx and œsophagus, at other times a paralytic inertia of the whole respiratory apparatus, occurring either primarily or following the spasmodic attacks. The patient may die either from respiratory spasm or from syncope. On the other hand, hysterical pseudo-hydrophobia is not uncommon, and I have seen several instances of this in which the patient erroneously thought that he had been bitten by a rabid dog. Here we observe globus hystericus with rapid breathing and various dramatic movements of the trunk and limbs, sometimes accompanied by a loud hysterical laryngeal noise intended to resemble a dog's bark. But there is neither true respiratory spasm nor paralysis, and to the careful observer the diagnosis presents no difficulties.

Epilepsy, Chorea, Paralysis Agitans.

There are also other nervous diseases in which the respiratory mechanism may be upset. For example, in a major epileptic fit the tonic phase of the fit is often ushered in by a curious laryngeal wail, the so-called epileptic cry, produced by tonic spasm of the expiratory muscles. Throughout the tonic stage of the epileptic fit the respiratory muscles are fixed, respiratory movements cease, and the patient becomes increasingly blue and cyanosed. Then, when the clonic stage sets in, the cyanosis passes off, the respiratory muscles take part in the jerking movements, and saliva may be jerked from between the lips. I once had the opportunity of doing a laryngoscopy during the clonic stage of an epileptic fit and was able to see the glottis alternately opening and shutting, synchronously with the clonic jerks of the trunk and limbs.

Both in athetosis and in chorea the irregular involuntary movements may implicate not only the limbs and face, but also the respiratory muscles, causing the breathing to be irregular and clumsy, so that the diaphragm and intercostals no longer contract synchronously and the smooth rhythm of respiration is interrupted. In consequence, even the patient's articulation may be jerky. In so-called "paralytic" chorea the superadded factor of muscular feebleness may sometimes be so severe that the patient's voice is reduced to a faint whisper.

The fine muscular tremors of the limbs in exophthalmic goitre may sometimes spread to the trunk and to the respiratory muscles. This tremulous respiration, as Minor pointed out, is best marked during a long expiration.

In advanced paralysis agitans, if we examine the patient laryngoscopically, we may observe a rhythmic tremor of his vocal cords, synchronous with the tremor of the limbs. This laryngeal tremor usually ceases during phonation, but not always. The patient's voice becomes thin, monotonous, and feeble. His articulation, like his gait, becomes festinant, so that he begins his sentences slowly but tends to hurry towards the ends of sentences or of long words, pronouncing the final syllables hurriedly.

Hysteria, Habit-Spasms.

Various respiratory phenomena may be met with in hysteria. Of these, hysterical cough is the commonest, but hysterical tachypnœa or rapidity of respiration, hysterical sobbing, also all sorts of curious laryngeal noises, may be met with in different cases. But, whatever their variety, all these hysterical respiratory affections cease spontaneously during sleep. Hysterical cough occurs almost always in bouts or paroxysms, often at the same special time of day, and most frequently when the patient knows herself to be under observation. It may last for hours at a time. Hysterical cough is unaccompanied by true dyspnœa, whilst abnormal physical signs in the respiratory organs are conspicuous by their absence. Hysterical cough often has a peculiar metallic musical sort of noise. Hysterical laughing or sobbing are frequently part of a hysterical paroxysm, whether occurring before, during, or after the hysterical attack. Hysterical tachypnœa is another fairly common manifestation, consisting in paroxysms of extremely rapid breathing (80, 100, or even 150 per minute), but without cyanosis or other respiratory distress. The pulse remains quiet and steady throughout the attack, there are no abnormal physical signs in the chest, and the temperature remains normal throughout. Hysterical aphonia, another common type, is easily recognised, not only by its concurrent phenomena, but by its characteristic laryngoscopic appearances, showing deficiency of adduction of the vocal cords.

Finally, we have the interesting group of respiratory tics or habit-spasms, which occur in highly strung, often highly intelligent individuals of psychasthenic nervous constitution. Such patients are not necessarily mentally subnormal; on the contrary, some of them are far above the average of intelligence. Respiratory tics are of many varieties. I recall one individual—a distinguished university professor—whose habit-spasm consists in an occasional sudden sniffing inspiration accompanied by wrinkling up of the nose; another individual—a surgeon of world-wide reputation—who makes an occasional sudden inspiratory laryngeal noise from time to time when talking. In another highly strung young man the breathing is interrupted at irregular intervals by paroxysms of short little expiratory puffs at the rate of about two per second, associated with grimacing and with

Morbid Conditions Underlying these Infections.

Chronic infections do not arise in the normal alimentary tract. Derangements, often of a very gross nature, were traced in more than 90 per cent. of the present series.

1. Stagnation is almost universal. Three-quarters of the patients had suffered from constipation for many years prior to the onset of the arthritis and in almost one-half of these cases the constipation had been very severe. As measured by means of an opaque meal and X rays, stasis was found as commonly in the small bowel as in the large. In the colon it occurred in 89 per cent. of cases, the average time taken for the evacuation of the greater part of the meal in these cases being more than three days, while in some instances a week was required. In the ileum stasis was found in 90 per cent. of cases. In these the average time required for the ileum to empty, after all the barium had left the stomach, was eight hours, whereas under normal circumstances only three and a half or four hours are needed. Stasis was not so common in the stomach and only occurred in one-third of the cases. The average time taken for the meal to pass through the stomach was eight hours, or twice the normal time. In many of the patients repeated overloading of the colon over a period of years had led to compensatory hypertrophy with elongation. Three-quarters of the patients had long redundant loops of pelvic colon and in two-thirds the transverse colon was doubled in length and hung in a tortuous festoon across the abdomen. Many patients had developed secondary obstructions which aggravated the primary stasis. One half of them had a kink in the last coil of ileum. One-third had a very acute splenic flexure in the erect posture and as many as 90 per cent. had a "last kink" in the pelvic colon. The appendix was examined at all laparotomies and whenever the opaque meal entered and displayed its shadow on the fluorescent screen. It was abnormal in three-quarters of these cases. Sometimes it was the seat of chronic inflammation, but more frequently it was fixed to the posterior abdominal wall and acted mechanically by interfering with the passage of the food through the last coil of ileum.

2. Ptosis had occurred with great frequency to the hindrance of peristalsis and the free flow of blood and lymph. For the purposes of this description only outstanding examples in which the ptosis was so severe as to be beyond all dispute have been noted. In 51 cases the greater curvature of the stomach was within an inch of the symphysis pubis in the erect posture, in 133 cases the cæcum was deep in the pelvis. In an equal number the hepatic flexure was in the right iliac fossa and in about the same proportion of cases the transverse colon fell to the level of the symphysis pubis.

3. Ferment action was commonly defective and digestion slow, so that much unassimilated food found its way into the large bowel where it formed a suitable nidus for bacterial activity. The production of an excess of gas affords the most direct evidence of such activity and 130 of the patients complained of this undue flatus in the colon. A similar proportion complained of gastric symptoms which were of many different kinds and varied in severity from heartburn and nausea to vomiting and acute epigastric pain after meals. As a group these symptoms indicate the great frequency with which errors of digestion in the stomach and duodenum occur in arthritic patients.

4. Apart from bacteriological analyses much direct evidence of infection of the colon was forthcoming. Intermittent looseness of the bowels, short attacks of severe diarrhœa, and the repeated passage of mucus were of common occurrence, whilst in a small minority of cases persistent diarrhœa replaced the more usual constipation. A history of one or other of these varieties of diarrhœa was given by 67 of the patients.

5. In certain cases there were gross defects of other kinds in the alimentary tract. Chronic gastric ulcers were seen in 17 per cent. of those cases upon whom high laparotomies were performed and histories of recent severe hæmatemesis was given by 2 per cent. of the other patients. Gall-stones were found at 11 per cent. of high laparotomies and typical histories of gall-stone colic were given by 3 per cent. of the remaining patients.

Masked Stasis and Hidden Sepsis.

Study of this series has shown again and again that stasis and sepsis can exist in the intestine and yet not be manifest without investigation. The bowels may act every day in spite of serious delay in the colon. The residues from the meals of the preceding 24 hours are not evacuated, but are stored up by such patients and passed out at the forty-eighth or seventy-second hour, as the case may be. The colon always contains the accumulated debris of two or three days' meals. In other cases the latent stasis is in the ileum, where the food may be retained for twice the normal time before it is passed into the cæcum. Such a delay does not of necessity interfere with the regularity of defæcation or give rise to discomfort in the abdomen. Marked stasis of these types is at once brought to light by systematic radiography, but cannot be detected readily in any other way. Sepsis in the bowel is just as frequently masked. Even extensive invasion of the bowel by infective bacteria such as streptococci does not always produce diarrhœa or any other sign of irritation. The true nature of these cases can only be detected by serological tests and the examination of cultures of the stools. Serious streptococcal infection of the ileo-cæcal region sometimes occurs even when the flora of the fæces appears to be normal. Such cases have frequently been investigated at laparotomy when samples of chyme could be obtained from the small intestine. In other cases they can be detected by giving the patient an ounce of lactose, a drachm of magnesium sulphate, and the juice of a lemon in water before breakfast on three consecutive mornings and examining the stools which are passed on the third day. The lactose reaches the colon and promotes the growth of streptococci which are hurried onwards so rapidly by the magnesium sulphate that they can be recovered from the stools.

In brief, it can be stated that stasis often occurs in the colon although there is a daily evacuation; stasis often occurs in the ileum, even when the patient does not refer any symptoms to the alimentary tract; streptococcal infections are often present in the bowel, although there are no symptoms of irritation of the colon, and extensive infection of the ileo-cæcal region does not always lead to the excretion of living streptococci in the fæces.

Results of Treatment.

The condition of the alimentary tract dominates the outlook in rheumatoid and osteo-arthritis. The general scheme employed in the treatment of the present series of cases has been as follows. The entire alimentary tract was surveyed carefully in each case and an estimate formed of the relative degrees of septic absorption occurring at the various levels. The more accessible areas of infection in the jaws, throat, and intestines were treated surgically, and all the disorders of the digestive tract which had encouraged the development of chronic infection were dealt with. Autogenous vaccines proved of great value when used to supplement these measures. They were prepared from infective bacteria of all the principal zones of sepsis. Streptococci obtained from different foci in the same patient usually vary in their cultural characters, and each strain was included in the vaccine. Chronic infection frequently damages the thyroid gland. In the present series minor forms of subthyroidism were very common, whilst well-defined myxœdema or goitres of considerable size were seen in 14 per cent. of cases. There is an intimate association between immunity reactions and the functions of the thyroid gland. The dry extract of the thyroid was given in all such cases with great benefit to the joints. Accurate diagnosis, aided by radiography and bacteriology, makes radical treatment and cure possible. In the present series of cases, which have been followed for varying periods up to nine years, 80 per cent. show very great above had given such proof of flying proficiency that it would be manifestly unfair not to accept them at once in spite of their disabilities, especially in the absence of any present or past complications of their disease. Their middle ears were not healthy, but they had always been serviceable enough for efficiency, and the public would have been losers by the rejection of such men. It should here be added that particular stress is laid during the examination on a concomitant search for any internal ear trouble that may be present, as also on the presence or absence of exacerbations of middle-ear disease at any time in the past history. The regulations also provide an additional safeguard—viz., periodic medical examinations at maximum intervals of six months.

Auditory Acuity.

What is efficient flying auditory acuity? The importance of hearing to airmen lies largely in the fact that they may be able to detect engine defects and to use telephones, but of course hardness of hearing is a serious handicap to success in almost any trade or profession. The following are among those who presented themselves for examination:—

1. P. Had 2300 hours previous flying. Hearing nil in right ear, normal in left. Right ear trouble, dating from age of 10, due to an old chronic catarrh. As a fighting pilot this man would have been at a disadvantage in having imperfect ideas of direction of sounds, such as those made by shells and bullets, but because of his past record he was considered quite trustworthy as a civilian pilot, and was accepted.

2. P. In civil life an airman and engineer, 2000 hours previous flying. Right drum retracted and opaque, but good hearing on that side. Left ear ran in childhood; hearing practically nil on this side, there being an old healed suppurative otitis media with a retracted adherent membrane. Same view taken as in Case 1.

3. S. In civil life an airman, 3000 hours previous flying. Right ear absolutely deaf for last nine years; no reason could be given or cause found. Left ear normal. Similar view taken as in Cases 1 and 2.

4. K. In civil life a test pilot, 3000 hours previous flying. Hard of hearing in both ears from childhood; hears a loud voice in right ear at a distance of only 2 ft., and in left ear at a distance of about 1 ft. Both drums retracted, scarred, and opaque, but no signs of active disease. Vestibular reactions are normal. Particularly alert, a good lip-reader, and has excellent testimonials from his firm. Flown successfully for five years, instructed for a considerable time at a civilian school, acted in the army as instructor, test pilot, and ferry pilot, and since 1917 has tested all experimental machines and numerous others of a well-known firm.

This last-mentioned case of bilateral hardness of hearing is particularly interesting; in spite of his handicap the airman learnt to fly successfully, and confidently asserts that he can at once detect any change in the noise of his engines. He is of exceedingly active mentality and his other senses are extremely acute. He was accepted in view of the previous successful flying history.

Vestibular Mechanism.

If by "intact vestibular mechanism" is meant a vestibule where no pathological process is or has been present, candidates whose vestibular mechanism is or has been so involved should be rejected. The phrase "unduly hypersensitive or hyposensitive" is open, however, to much more dubiety, and in the present state of our knowledge there are diverse opinions as to its correct definition. According to Colonel Isaac Jones, in his book entitled "Equilibrium and Vertigo,"[1] the Americans during the war laid very great stress on the Bárány tests, and actually rejected candidates with a nystagmus period of under 16 seconds or over 36 seconds, after a period of rotation to right or left, consisting of ten turns in 20 seconds. They have apparently modified this arbitrary rule, according to their official publication of February, 1920.[2] In regard to efficient service pilots at the front, Sydney Scott showed that the reactions of the semi-circular canals do not serve to indicate a pilot's flying ability,[3] and Bilancioni says that in normal individuals the nystagmus varies between extremely ide limits.[4]

In a paper of my own on the subject of labyrinthine reactions published last year[5] I showed that some of our most experienced pilots failed to satisfy American rotation standards, and concluded that "in the absence of a discovery of present or past signs or symptoms pointing to an aural affection, routine examination by means of the Bárány tests is superfluous, provided that a thorough medical examination is made." With regard to rotation tests, the Aviation Candidates Medical Board of the Royal Air Force is inclined to lay very much more stress on the ability to perform certain simple acts immediately *after* a period of rotation, as also on a history pointing to hypersensibility to motion in trains, swings, or ships—i.e., to what are apparently excessive labyrinthine symptoms; such hypersensibility is always carefully noted and a thorough labyrinthine examination made, especially of individuals who have trouble while flying or are without previous flying experience. In connexion with the ability to fly with an apparently unsatisfactory condition of the labyrinthine mechanism the following two cases of civilian pilots examined are interesting:—

1. B. Previous flying hours, 900. Never could stand the sensation on swings and merry-go-rounds, and always feels ill at sea. Impossible to carry out Bárány tests on him, because on rotation he immediately felt ill and begged to be stopped. Nose, throat, and ears normal, Eustachian tubes pervious. Had a crash in October, 1916, with slight concussion, and since suffered at times from nervous debility. In 1919 flew successfully as a pilot; the history of concussion places one in doubt as to whether the symptoms were purely cranial, or labyrinthine, or both. Incidentally he was a heavy cigarette-smoker.

2. K. Number of flying hours, 250. In spite of this cannot stand being rotated; very quickly feels ill, and in boyhood never liked swings or roundabouts, being too much upset by the motion. No cause could be found for this hypersensibility which, however, has not interfered with his flying career.

The above two cases could be multiplied, but it must be remembered, and indeed practically every experienced pilot will agree, that the motion and effects of the rotary chair are quite different from those of an aeroplane, and the symptoms produced thereby very much greater and more intense. It is almost impossible to make a fair comparison of the two forms of motion, as the chair, unlike the aeroplane, spins round in a small axis in the horizontal plane, and also because the labyrinthine effects produced thereby arise most markedly just after rotation is stopped, there being, of course, no such deliberate stoppage of an aeroplane.

We now turn our attention to the nose and throat, and consider the regulations, or rather indications, with reference to the state and fitness of the upper respiratory tract. It is here, indeed, that we find in practice most exception to theoretical considerations. "The aeronaut must possess free nasal entry on either side" say the international requirements: "mouth-breathing constitutes a serious flying disability" says the Aviation Candidates Medical Board, R.A.F. My statistics of these 450 experienced pilots tell us, however, that 32 of them were mouth-breathers in all degrees ranging from partial or occasional to permanent, and that only one of these 32 was rejected on medical grounds and then not because of mouth-breathing; the other 31 were good pilots with good records and were deservedly granted licences.

Free Nasal Air-entry and Mouth-breathing.

For the moment it will be convenient to consider the above 32 cases together; later it will be necessary to consider others where mouth-breathing was definitely secondary to a cause obviously present at the time of examination in the nose or throat and almost crying out for remedy. In the cases of these 32 it was rather different; in some there was an associated more or less marked septal deviation, and in others diseased or hypertrophied tonsils or adenoid remains were discovered; but it must be said that not one of them had any other signs or symptoms of nose and throat disease. In these cases one did not feel justified who have done many mastoid operations for chronic middle-ear suppuration know how lengthy the after-treatment of these operations may be—sometimes extending into many months—a discharge even then frequently continuing for years. With a view to shortening this period, I have employed ionisation as part of the after-treatment for some considerable time. Among other advantages of its use are the following: (*a*) it causes a reduction of the inflammation; (*b*) it cleans up the wound; (*c*) it lessens pain, and so makes the dressing less objectionable to the patient.

In this treatment the question arose of its duration after operation. I have treated a fair number of cases in this way; a few statistics given below may be of interest. The shortest time after operation that has elapsed before administration of ionisation in my own cases is two weeks.

Results.

Speaking generally, the results so far indicate that cases ionised soon after operation clear up more rapidly than those ionised later; these again clear up in a shorter time than those which are not ionised at all.

The following statistics show results obtained by me during the past two years.

For the period 1920–21: number of mastoid operation cases ionised, 158; number of successes, 138 (=87·3 per cent.). By "success" is meant the curing of the suppuration and the healing of the wound. Of these cases 119 had 1 ionisation, 28 had 2 ionisations, 5 had 3 ionisations, 3 had 4 ionisations, and 3 had 5 ionisations.

The total length of after-treatment (of a series of 64 of the more recent cases) from the day of operation to the day of successful ionisation, was 700 weeks, which gives an average per case of 10·9 weeks. Of these 22 cases were dry under 10 weeks and of these 22 cases 2 were dry in 5 weeks, 4 in 6 weeks, 5 in 7 weeks, 6 in 8 weeks, and 5 in 9 weeks. All these early cases had one ionisation only with the exception of two cases, which were ionised twice.

For the period 1919–20: Number of mastoid operation cases ionised, 118; number of successes, 80 (=67·7 per cent.).

It is very difficult to obtain exact information of the percentage of successes after mastoid operation from *hospital* cases; but so far as I have been able to ascertain, the percentage generally is very much below that shown in the above results. The lower percentage for the period 1919–20 is probably due to the fact that the cases during this period were not ionised so early as those of the period 1920–21. The above percentage of successes must be considered very satisfactory, especially when it is remembered that the material is some of the worst in London.

The objections, from the patient's point of view, to ionisation are not serious. Many patients feel nothing at all, some complain of a feeling of heat or slight burning in the ear. Others complain of giddiness—generally when the current is being turned on or off, particularly the latter, and more especially if it is done too quickly. Occasionally actual vomiting is produced but this is rare. Practice, however, shows that the disadvantages are hardly worth considering, while the advantages are great. There is a big field for this work, and its extension may be strongly recommended.

GLASGOW WESTERN INFIRMARY.—The report of this infirmary, which was submitted to the annual meeting of subscribers on Dec. 7th, showed that in spite of increased public support, expenditure exceeded ordinary income by £26,307. In order to make up this deficit it was necessary to use the balance of extraordinary income received from legacies, to appropriate the whole sum of £6144 subscribed by special appeal, and also to draw from the stock account £654. This year the ordinary expenditure of £102,716 exceeds last year's, but the downward trend of prices encourages the hope that the maximum expenditure has been passed. The managers have been obliged to obtain an overdraft from the bank which amounts to £16,593, and in view of the seriousness of the position are appealing to all classes to continue and, if possible, to increase their support of the infirmary. The daily average of in-patients treated was 557, and the average cost per patient per day was 9*s.* 11*d.*, as against 9*s.* 3*d.* last year.

THE NORMAL LIMIT OF AGGLUTINATION FOR *B. DYSENTERIÆ* (FLEXNER)

AND THE SENSITIVENESS OF SUSPENSIONS.

BY A. D. GARDNER, M.D. OXON., F.R.C.S. ENG.

(*From the Department of Pathology, University of Oxford, Standards Laboratory under the Medical Research Council.*)

IN an article on the Ætiology of Bacillary Dysentery in Asylums in THE LANCET of July 30th, Dr. W. S. Dawson and Dr. W. Moodie describe the results of a number of agglutination tests of the blood of dysentery cases. These tests they performed with two types of bacillary suspensions, the one a "Standard culture" from the Standards Laboratory (Medical Research Council) at Oxford, the other obtained from Prof. L. S. Dudgeon. They state that:—

> "With the Oxford antigen, the first trace of agglutinins appeared at the end of the sixth week, and the agglutinins had disappeared at the end of the fourteenth week; while with Prof. Dudgeon's antigen agglutination began to appear at about the beginning of the fourth week, and had disappeared at the end of the fourteenth week also. Maximum agglutination was obtained with Oxford antigen between the eighth and tenth week, and with Prof. Dudgeon's antigen in the seventh week."

Comparison of Suspensions.

The authors refrain from expressing an opinion as to the relative merits of the two suspensions, yet an unbiassed reader of their paper could only judge Prof. Dudgeon's antigen to be a more serviceable material than the standard cultures issued from Oxford. It was therefore desirable to discover whether the apparent superiority were real, and, if so, on what it depended. To this end, and by the kindness of Prof. Dudgeon, I secured a sample of antigen made in the same way and with the same culture as that used by Dawson and Moodie. The strain of Flexner bacillus used in its manufacture is known as Flexner Gallipoli, of which a living culture was also sent to me.

The antigen was apparently a saline suspension of the bacillus, with a preservative added, but the details of its making are unknown to me. Its density was much (somewhere about three times) greater than that of "standard" dysentery cultures which vary round about 500 millions per c.cm. Tested with standard dysentery Flexner (V) serum it gave first-rate flocculation up to a dilution between two and three times greater than was given by the standard culture (Flexner V 12) used in comparison. *Prof. Dudgeon's antigen thus proved to be a suspension of great sensitiveness.* At the same time it betrayed no tendency to spontaneous flocculation.

A broth culture had been made a few days previously with the living Flexner Gallipoli (formalised 0·1 per cent.) and diluted to the opacity of standard cultures. This suspension was included in the test last mentioned, and proved to be slightly more sensitive than Dr. Dudgeon's suspension. *In figures, standard* agglutination (marked flocculation without sediment) occurred *with the standard culture at a dilution of* 1 in 625, with Prof. Dudgeon's suspension at 1 in 1500, and with *formalised Flexner Gallipoli suspension at* 1 in 1800. The stock Flexner culture used in the Standards Laboratory never produces suspensions of such great sensitiveness. *Clearly, then, the strain Flexner Gallipoli tends to give rise to suspensions of higher agglutinability than that of the Oxford cultures.*

The next step was to determine the serological characters of Flexner Gallipoli. With this purpose in view the three suspensions mentioned above were all tested at one and the same time with each of the five type serums which are made in the Standards Laboratory—viz., B. Flexner "V," "W," "X," "Y," and "Z."

The results are given in the table which shows the dilutions at which standard agglutination occurred in every case. When in any particular series of standard agglutination did not actually occur in any

ALIMENTARY INFECTIONS IN CHRONIC ARTHRITIS.

BY N. MUTCH, M.D. CANTAB., F.R.C.P. LOND.,
ASSISTANT PHYSICIAN, GUY'S HOSPITAL.

THIS communication is based upon an analysis of 200 personally investigated cases, of which half were hospital patients and the other half private patients, so that many different walks of life are represented. Gout, venereal or tuberculous disease of the joints, and all cases of monarthritis have been excluded, but no other selection has been exercised, and with these exceptions the cases may be regarded as consecutive. Although uniform infection of the whole alimentary tract is never encountered, multiple areas of infection are often found. They can be divided roughly into an upper zone which includes the mouth and throat, and a lower one which comprises the bowel and its appendages. In the present series, active sepsis was present in the throat and nose in 34 per cent. of the cases, and around the teeth in 52 per cent., whilst infective streptococci were recovered from the fæces of 84 per cent. The great importance of the lower zone has been shown very clearly by Sir Arbuthnot Lane and is well demonstrated by the two following cases:—

CASE 1.—In this instance absolute cure followed the removal of the infected colon, although areas of chronic infection in the tonsils were left untreated. M. H., a woman of 28, had suffered from severe constipation since infancy and from rheumatic arthritis for 15 years. All her joints were affected. Her colon was removed in 1913 and liquid paraffin taken as a routine measure afterwards. No other treatment of any kind was employed. She became free from pain after a few days and has never had any more pain or swelling in her joints up to the present date. She has gained four and a half stones in weight, can bathe in the sea with impunity, and leads a very active life with a normal feeling of vigorous well-being.

CASE 2.—This patient's arthritis was cured by colectomy although he had pyorrhœa alveolaris which was left untreated. H. M., a boy of 13, had been constipated for many years and had had rheumatoid arthritis for 15 months affecting knees, ankles, elbows, and jaw. There were pyorrhœa pockets between the gums and teeth and radiograms showed involvement of the periodontal membrane. Colectomy was performed and the pain left his joints. During the next few months a flexion contracture of the elbow straightened itself without any manipulations, and now, five years later, he is a well-developed young man following a laborious occupation and with no trace of his former joint trouble.

Comparison of Forms of Infection.

Doubtless at times much injurious infection takes place from the tonsils and jaws, but the invasion from the bowel is of a much more serious nature. Numerous instances can be found in which chronic arthritis has commenced many years after the extraction of all the teeth. This had occurred in 15 per cent. of the present cases, the period which had elapsed between the extractions and the onset of arthritis varying from two to 20 years and the average time being 11 years. It is clear that in these patients invasion of the joints must have taken place from some other mucosal focus. Another 16 per cent. had had total extractions done during the course of the arthritis and yet continued to have outbursts of arthritis with the involvement of fresh joints. Almost all the extractions had been done for gross septic conditions. Critical analysis of the throat histories shows a similar state of affairs. Four per cent. of the patients had had their tonsils enucleated many years before the onset of the arthritis, and another 5 per cent. had received no benefit from enucleation carried out during the course of the disease. The remaining 91 per cent. still possessed their tonsils. If this inquiry is taken one step further it is easy to find patients with continued arthritis who are both edentulous and devoid of tonsillar tissue. The explanation of the failure in the treatment of these patients lies in the infection which was taking place from the lower zones in the bowel and which had been neglected during the cleansing of the mouth.

Localised and Diffused Infections.

Anatomically the lower zones of infection can be divided into two groups. In the first group are localised infections. Mechanical agents, such as hard fæces, obstructions, stasis, ptosis, and distension with gas produce loci of depressed resistance through attrition, local poisoning of the mucosa, and interference with the flow of blood and lymph. In these places infective bacteria establish areas of chronic infection in the wall of the bowel. Stercoral ulcers, diverticulitis, ulcerated piles, and chronic appendicitis are common examples of this type of infection. In the second group there is a diffuse infection which sometimes involves the whole intestine from duodenum to rectum, and may or may not be associated with circumscribed zones of special activity such as have been placed in the first group. A further description of this common type of case is given later in the paper.

Most of the infections are streptococcal, but a few are staphylococcal. In the present series the latter were only 4 per cent. of the whole.

Staphylococcal Infections.—The two following cases are typical examples:—

CASE 3.—D. W., a boy aged 5, had suffered from constipation since birth and from Still's disease for two years. His hips, knees, ankles, wrists, and elbows were seriously involved. He had much intermittent pyrexia with rigors. Blood cultures yielded a pure growth of *Staphylococcus citreus*. Cultures taken from his ileum during a laparotomy also gave a growth of the same organism.

CASE 4.—F. P., a woman of 27, had for three years suffered from rheumatoid arthritis of the fingers, wrists, knees, and spine. Stasis occurred in her ileum and colon. At laparotomy her mesenteric glands were seen to be acutely enlarged. Cultures from them gave a pure growth of *Staphylococcus aureus* and similar organisms were obtained from the contents of the ileum.

Streptococcal Infections.—In this widely distributed group are included infections by many different types of streptococcus, and only 6 per cent. of the present series were hæmolytic. In about one-third of the cases abnormal forms of the colon bacillus of the non-lactose-fermenting or late-lactose-fermenting varieties were found in association with the cocci. In the diffuse infections the streptococci are distributed along the alimentary tract in a definite pattern. In the pelvic colon they are much less numerous than the colon bacillus. In the ileo-cæcal region they become more conspicuous and at the higher levels are usually present in pure culture. The table illustrates this distribution. In the second column are given the averages of analyses carried out on 21 patients from each of whom serial cultures were made at several levels at laparotomy. The pattern was the same in each of the 21 cases. In the third column are given the averages of analyses made on a much larger number of patients. In this series many cases are included in which an analysis was made at one level only. Again the same pattern can be seen. Streptococci predominate in the small bowel and the colon bacillus in the large bowel. The precise level at which transition takes place from streptococcal to *B. coli* dominance varies in different patients, probably on account of variations in the chemical nature of the contents of the bowel determined by differences in diet, peristalsis, and ferment efficiency. The point of transition is usually in the ileo-cæcal region, but may be on either side of the ileo-cæcal valve.

Showing Ratio of Streptococcus Longus to B. Coli.

Site.	Averages of 21 serial analyses.	Averages of all analyses.
Duodenum	100·0	100·0
Jejunum	100·0	100·0
Upper ileum	80·20	83·17
Lowest ileum	46·54	41·59
Cæcum	24·76	18·82
Pelvic colon and fæces	3·97	14·86

results seems to be that they made use of a technique of insufficient delicacy.

In conclusion, it may be well to state that the "normal limit" of dysentery agglutination has only been established for the "V" type of Flexner's bacillus (in addition to the Shiga bacillus). It has been assumed that it is approximately the same for the other types. Experimental proof is, nevertheless, clearly desirable, and is being taken in hand at the present time.

Summary.

(1) The different results obtained by Dawson and Moodie in their serological tests with Prof. Dudgeon's "Flexner" antigen and with Oxford standard culture depend on the fact that the strain "Flexner Gallipoli" used by Prof. Dudgeon yields suspensions of much greater sensitiveness than that of the standard cultures.

(2) Flexner Gallipoli is otherwise serologically identical with the Flexner (V) strain used in making the standard cultures.

(3) Just as specific serums give a much higher titre with Flexner Gallipoli suspensions than with Oxford standard cultures, so do normal serums.

(4) Owing to the presence of "Flexner" agglutinins in normal serums, highly sensitive suspensions are, for the purposes of clinical diagnosis, of no greater value than those less sensitive.

(5) The limit of normal agglutination of a suspension or set of suspensions must be determined before they are employed in serodiagnosis. In other words, standardised suspensions and a constant technique are essential for this work.

CASES OF
INFECTED KNEE-JOINT
TREATED BY INCISION, DRAINAGE, AND MOVEMENT.

BY PHILIP WEATHERBE, M.B., CH.B. EDIN., F.A.C.S.,
LECTURER ON OPERATIVE AND DIDACTIC SURGERY, DALHOUSIE UNIVERSITY; SURGEON TO THE CHILDREN'S HOSPITAL, HALIFAX, N.S.

DURING 1912 a boy, aged 9, was sent to hospital from the country, with his knee in plaster-of-Paris at almost a right angle, which turned out to be a case of syphilitic chondro-arthritis of the knee-joint. An X ray showed clearly destruction of cartilage and sclerosis of bone in the femur. Other manifestations of the disease in this boy included tibial periostitis, husky voice, bifid uvula (from cicatricial contraction following old ulceration), nasal discharge, with destruction of nasal bridge, blocked nasal duct discharging pus into inner canthus of eye, deafness, and slight iritis. The patient was placed under good hygienic conditions and given nutritious food and tonics—i.e., cod-liver oil with the syrup ferric iodide followed by mercurial and potassium iodide treatment. After a short interval the knee-joint was explored by free incisions on either side of the patella. The diseased cartilage, which was eroded in a serpiginous manner, was scraped and sequestra removed from the lower end of the femur with the least possible interference with the epiphysis; the synovial membrane was diseased, swollen, and œdematous, and some of this granulation tissue was also removed. The joint was irrigated and rubber drainage-tubes inserted into and through the knee-joint. Continuous drainage was then applied by means of wet boric compresses covered with oiled silk, as the best and most convenient form of continuous drainage. The ultimate result of this case, as far as the knee-joint was concerned, was perfect. He was shown before the Medical Society of Halifax in 1912, with a knee-joint normal in every way, excepting for the scars on either side of the patella.

Application of Same Treatment to Septic Knee-joints.

The functional result of the above case led me to try the same kind of treatment upon septic conditions of the knee-joint. The first opportunity (in 1914) was a septic knee-joint, which followed an operation for removal of semilunar cartilage and went septic through faulty technique, with all the symptoms of acute virulent infection—with marked swelling, high temperature, pain, and septic absorption. The joint was treated in the manner already described above. After acute inflammation had subsided, passive movement of the joint was carried out; almost full flexion and extension eventually became possible.

The following two cases, one in April, 1916, the other in September, 1920, were very similar to one another in all respects, the ultimate result being a perfectly functioning joint in each case. One, a boy aged 8, fell upon a needle which pierced the joint, causing it to swell and become painful with a resulting septic knee-joint full of pus, which was opened 21 days after the accident. In the other case infection was more virulent and symptoms were more severe; this case was treated more energetically and boldly than the others, and I think responded more rapidly to treatment. The patient was a child of 4, who was stabbed in the knee-joint with a knife. This immediately resulted in all the symptoms of acute infection in the joint, acute pain, swelling, redness, heat of the part, high fever (104°), quick pulse, and symptoms of septic absorption. The joint, opened on the day following the accident, was full of sticky dark serous fluid with marked redness and injection of the synovial membrane, including cobweb adhesions in the synovial pouch above the patella, with flakes of lymph in the joint. The entrance wound was dirty-looking and sloughy. The time occupied in treatment of these two last cases was about two months; both were shown before the Halifax Medical Society in February, 1921.

Conclusions.

The conclusions I have drawn, from my observation of the above cases and from perusal of recent literature upon the subject of septic knee-joints, are that when the diagnosis is septic knee-joint, the treatment should be at the earliest possible moment a free opening of that joint by lateral incisions four to six inches long, on either side of the patella, followed by thorough irrigation of the joint, breaking down of all adhesions, manipulation by full flexion and extension, introduction of several rubber drainage-tubes about the size of the little or big finger according to the size of the patient, application over the wounds of wet boric lint covered with oiled silk, and creation of continuous drainage of the joint by capillary action. The dressing should be changed once a day with removal of tubes, irrigation, and full flexion and extension. This treatment should be repeated daily until the wounds are healed. Other observations I have made lead me to suppose that failure will occur if any of these details are not observed—i.e., if incisions are not large enough, and if the joint is not fully flexed each day, or if the dressings are not kept wet or are discontinued before the wound has thoroughly healed. The changing of dressings and movement of the joint are comparatively painless. This method of treating septic knee-joints apparently gives the patient the best chance regarding his life and the function of his limb.

DR. Edward Burdett Pooley and Dr. Leonard Greenham Starr Molloy, D.S.O., have been appointed Knights of Grace of the Order of the Hospital of St. John of Jerusalem in England.

DONATIONS AND BEQUESTS.—Mr. Emmanuel Shackleton, of Littleborough, left £1000 each to Rochdale Royal Infirmary, Manchester Royal Infirmary, and Dr. Barnardo's Home.—The late Sir Frank Bowden has among other bequests left £1000 to the Nottingham General Hospital.—Under the will of the late Mr. James Parkinson the Royal National Pension Fund for Nurses will benefit by a sum of more than £20,000.

improvement or complete arrest. Of the failures one-quarter had received very partial treatment only and could not be inoculated with vaccines. If it were possible to exclude those cases in which circumstances such as age, temperament, and position in life prevented the full use of radical methods the results would have been still more encouraging.

THE PROBLEM OF CHRONIC SUPPURATION OF THE MIDDLE EAR,

WITH SPECIAL REFERENCE TO IONISATION.

BY ARTHUR G. WELLS, M.B., B.S. LOND., M.R.C.S., D.P.H.,

MEDICAL OFFICER IN CHARGE OF THE NOSE, EAR, AND THROAT DEPARTMENT, LONDON COUNTY COUNCIL; CONSULTING AURAL SURGEON TO THE NATIONAL SOCIETY FOR THE PREVENTION OF CRUELTY TO CHILDREN, ETC.

THE disabilities resulting from the chronically discharging ear have recently claimed increasing attention from the profession. During the war, in the British Army alone, some tens of thousands of men were found to be suffering from this disease; among London County Council school-children there are over 12,000 "recognised" cases, and the actual number must be well in advance of this figure.

I wish in this short article to explore certain methods by which the disease may be dealt with and briefly to indicate my own experience in those methods.

Prevention.

For purposes of prevention of chronic middle-ear suppuration three separate and distinct periods must be recognised as preceding the condition, viz.: (*a*) the period before there is any affection of the ear; (*b*) the period when the ear is first acutely inflamed and before the drum-head has ruptured; (*c*) the period of acute middle-ear suppuration after rupture of the drum-head.

(*a*) *The period before there is any affection of the ear.*—Children should be taught to breathe correctly, to keep their noses in a cleanly state, and to live as hygienic a life, in all ways, as possible. A certain proportion of suppurating ears certainly originate in neglect in observing these rules.

(*b*) *The period when the ear is first acutely inflamed and before the drum-head has ruptured.*—If it were possible to treat all ears suitably in this stage of the disease, probably 90 per cent. would never pass into the stages beyond.

Several barriers at present prevent this early treatment. First, the public, ignorant of the importance of the condition, make no endeavour to obtain treatment at all; when the patient is eventually brought under the surgeon's care, the condition has advanced considerably beyond this stage. Secondly, too many practitioners would shrink from undertaking the delicate, though fairly simple and small, operation of incising the drum-head. Comparatively few students to-day, when they leave hospital, are capable of efficiently performing the operation of paracentesis, or, indeed, of recognising a normal drum-head. There should be no great difficulty in educating the practitioner in this respect; it remains to educate the public—a process most easily attained, perhaps, by an intensified campaign through the press.

(*c*) *The period of acute middle-ear suppuration after rupture of the drum-head.*—If ears were correctly treated in this stage, very few would pass on to chronic suppuration.

Treatment by Ionisation.

The routine treatment of discharging ears has long entailed the use of various drops, powders, lotions, &c., often carried on for months and even years without effecting a cure. Some cases after varying lengths of time have got well, possibly as the result of the atment, possibly in spite of it.

Ionisation consists of passing a continuous current through a Leduc's rheostat, the patient being placed in the circuit, and the positive pole (which can conveniently be made in the form of a vulcanite ear-speculum containing a metal band which does not come into contact with the skin) placed in the ear which contains some of the ionising fluid, while the negative pole is placed upon the patient's arm or leg. The exact details of this technique have already been published by A. R. Friel, Salisbury Sharpe, and others, and I will therefore not elaborate this point, but it would be well to emphasise the necessity of thoroughly cleansing the ear and removing all discharge, débris, &c., before attempting to ionise, otherwise failure is certain.

The ionising fluid generally used by myself is:—

$ZnSO_4$	5 g.
Glycerine	57 c.cm.
Water to	1000 c.cm.

Equal parts of the above and hot water are employed. If, however, the ear is sore and painful and the mucous membrane swollen, salicylate of zinc may be used as the ionising fluid, the negative pole being first used to produce the sedative effect of the salicyl ion, and then the positive pole to produce the action of the zinc ion on the tissues.

Ionisation has been established as one of the most valuable and satisfactory means known for treatment of these cases. The method has at present definite limitations, but in the near future some of these may be curtailed. The indications for ionisation in this disease as observed in personal experience of some hundreds of cases permit the following groups to be described as *unsuitable*: (*a*) cases which present large granulations and polypi in the tympanum; (*b*) cases where there is any disease of bone either of tympanum or mastoid; (*c*) cases where the antrum is diseased; (*d*) cases where there is disease of the Eustachian tube; (*e*) cases with any naso-pharyngeal condition favouring re-infection of the ear; (*f*) cases where perforation in the membrane is so small that fluid cannot pass satisfactorily from the meatus into the tympanum. With any qualifications applicable under these headings, it may be generally stated that cases suitable for ionisation are those where the ionising fluid can reach the whole area of suppuration.

It may be urged that most cases, if not all, of chronic middle-ear suppuration are not limited to disease of the tympanum, but that the antrum is also affected, and therefore ionisation is contra-indicated. As a matter of experience, however, the antrum is often so slightly affected that successful treatment of the tympanum by ionisation is not interfered with. My results obtained in various series of cases show a cure of the suppuration in percentages varying between 53 and 67, the whole averaging about 60 per cent. In some cases one ionisation is sufficient; in others two and even three administrations are needed.

Use of Ionisation in Diagnosis.

Besides being a valuable method of treatment, ionisation is also, in many cases, an important aid to diagnosis. It frequently happens that in examining an ear, a little pus can be aspirated from the antrum or aditus; it is hard to say definitely whether the antrum is too far diseased to hope for a cure by ionisation, and whether indeed the proper treatment should not be a mastoid operation. Ionisation frequently clears up this point; failure to effect a cure or any improvement justifies the assumption that disease of the antrum is sufficiently advanced to call for a mastoid operation. I have frequently used this as a deciding factor; the condition found on performing a mastoid operation has always fully justified this procedure.

Ionisation as After-Treatment.

This brings us to another use to which ionisation may be put, and which, so far, I believe, I have been alone in employing—viz., as part of the routine after-treatment of mastoid operations. All surgeons tion occurred, and several pieces of catgut and one of silk were discharged from the wound, but the patient made an excellent recovery. The aneurysm became quite hard. He had also ligatured the right subclavian and common carotid arteries for aorta aneurysm causing pressure on the trachea. The patient was relieved.

The PRESIDENT inquired why Sir Charles Ballance used kangaroo tendon.—Sir CHARLES BALLANCE replied that he had found that kangaroo tendon remained unabsorbed for 80–90 days, a period which could not be obtained by any method of preparing catgut.

Sir G. LENTHAL CHEATLE described

A New Operation for Inguinal Hernia.

Several cases in quick succession presenting difficulties in the efficient excision of the sac had led him to devise a new method by which these and other troubles could be easily and successfully dealt with when they arose. He approached and reached the back of the inguinal canal from a middle-line incision in the lowest part of the abdominal wall. Unless compelled by some complication he did not open the general peritoneal cavity, all the work being done in a space made in the subperitoneal tissue. He had operated in this way upon 41 patients. In the first nine all the incisions were longitudinal; in the remainder he had traversed the abdominal walls by Pfannenstiel's method.

The patient was placed in the Trendelenberg position and the operator stood on the side opposite the hernia. A transverse skin incision 4 or 5 inches long was made 1½ inches above the symphysis pubis, with its centre in the middle line. A similar incision was made in the aponeurosis of the rectus abdominis of both sides, care being taken not to injure either linea semilunaris. The linea alba was undercut upwards and downwards to within one or two inches of the umbilicus and to the symphysis; in doing so the sheath of each pyramidalis muscle would be opened. The opening thus made in the aponeurosis was retracted up and down, and the subperitoneal tissue exposed by separating the abdominal muscles in the middle line. The peritoneum and its contents were then pushed up on both sides, and, if necessary, kept up by packing. Two retractors were inserted on the side of operation. The retractors should have long, separate and blunt prongs. The lower retractor, by far the most important instrument in the operation, should pull the abdominal wall downwards, outwards, and forwards to lift up the abdominal wall. Its prongs should reach the deep epigastric artery and vein. Nobody should proceed with the operation until he was satisfied that this retractor was in its proper position. The upper retractor pulled the structures outwards. After more completely pushing upwards the outer part of the peritoneum and thoroughly exposing the iliac fascia it would be possible to see the neck of the sac entering the inguinal canal. The deep epigastric artery and vein were then delimited and separated from the inner part of the neck of the sac. Cheyne's dissector was a very useful instrument to use for this purpose. The spermatic veins and vas deferens with its vessels were found and separated from the whole length of the exposed sac. These structures were usually on the outer and under surface of the sac. The sac having been cleared it was pulled out of the canal by gentle continuous traction in the direction in which it lay. If there were no indications of the possibility of its easy extraction the sac was cut and the canal portion replaced. (Congenital herniæ would belong to this type.) The neck of the sac, including part of the parietal peritoneum, was then transfixed and removed. Finally the inguinal canal of the opposite side was examined, and if abnormalities existed they were treated on the same lines. He had only once had to ligature a vessel in the subperitoneal space, and that was a small branch of the deep epigastric vein.

Sir G. Lenthal Cheatle then described the complications and structures with which he had met, the herniæ he would avoid, and the herniæ he would select for this operation. He had found and removed unsuspected and potential hernial sacs from the opposite side in three patients. In others he had cleared from the internal opening of the canal firmly attached dimples of the parietal peritoneum. In others he had removed fibrous cords that passed from the parietal peritoneum into the canals. In one patient the urinary bladder occupied the canal and was practically a part of the neck of the sac. The peritoneum was peeled from the bladder and the sac was radically excised. When he met this complication again he would distend the bladder with fluid. This would render the separation of the peritoneum safer and easier. In seven cases he found the urachus which bore the same relation to the sac as the bladder. The urachus was traced to its union with the bladder; it contained a good deal of unstriated muscle, very tortuous patent arteries, and some fat. In a few patients he had traced adhesions between bowel and sac, and omentum and sac into the general peritoneal cavity which he had been compelled to open to clear them satisfactorily away. The herniæ in these instances appeared to be reducible before operation. The obliterated hypogastric artery was recognised in the sac in three cases. In one of these the lumen of the vessel was not obliterated at the point of section. Sir G. Lenthal Cheatle said that from one patient he removed a small sac entering the canal, and missed a much larger one that was plastered against the iliac fascia and outer part of the inguinal opening. It was this mistake that made it so essential to expose the iliac fascia. In another patient he had the following unfortunate experience. He had removed the sac on the left side and found an unsuspected sac entering the internal ring on right side. He congratulated himself on removing these two sacs from the same opening. In six weeks the patient returned with a direct hernia on the right side. Rightly or wrongly, he associated his operation with this new hernia, and determined to take Mr. Victor Bonney's advice and adopt Pfannenstiel's method of traversing the abdominal wall. As an unusual complication Sir G. Lenthal Cheatle mentioned that through the same opening he had removed an appendix from a patient who suffered from appendicitis and inguinal hernia.

The herniæ he would *not* select for this operation were direct hernia, irreducible enteroceles, hernia in male children under 7 or 8 years, and old herniæ in which the opening has been dragged down opposite the external ring. The herniæ he would select were those in females of any age, and all uncomplicated inguinal herniæ in males over 7 or 8. He would not exclude irreducible epiploceles. He had approached femoral herniæ by the same method, but the cases were too recent to be quoted as successes as yet.

Mr. MCADAM ECCLES inquired whether the patient should be regarded as cured by mere excision of the sac.—Mr. PHILIP TURNER said that he considered excision of the sac cured almost all herniæ, with only a few rare exceptions. In his practice he now restricted the operation to excision of the sac, except in cases of obvious weakness of the abdominal wall. This he had been led to do by the success of that operation in children, and he now considered it equally successful in adults. Sir G. Lenthal Cheatle's operation had the great advantage of rendering both inguinal regions accessible, and he intended to give the procedure a trial at the earliest opportunity.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.

THE ordinary quarterly meeting of this Association was held at the rooms of the Medical Society, London, on Nov. 22nd under the presidency of Dr. C. HUBERT BOND.

Dr. BEDFORD PIERCE, the chairman of the committee who have been revising the Handbook on Mental Nursing, presented to the meeting the revised handbook, setting out the improvements which had been effected. The cordial thanks of the meeting were accorded to the committee for their labours.

Dr. M. HAMBLIN SMITH, medical officer, H.M. Prison, Birmingham, read a paper on

The Medical Examination of Delinquents.

He said that John Howard's book on prisons in the eighteenth century showed that the medical side of prison administration was, at that date, practically type, the correct value is obtained by interpolation, using Dreyer's reduction table, which works accurately for dysentery cultures. The short series of tubes was used, as in the Widal test, and no great accuracy was aimed at.

Standard serums.*	V	W	X	Y	Z
Standard culture "V" 12	625	38	90	50	15
Flex. Gallipoli (Prof. Dudgeon's suspension) ..	1500	85	110	180	41
Flex. Gallipoli (new formolised suspension)	1800	110	150	220	34

* Each = 100 standard units for homologous culture.

It is clear enough from this table that Flexner Gallipoli is of the same group as (in fact is presumably identical with) the stock Flexner "V" of the Standard Laboratories.

The fact being established that "Flexner Gallipoli" is a "V" strain of unusual sensitiveness, but in other respects of normal character, it remained to consider whether the use of this strain for serodiagnostic suspensions (e.g., for the manufacture of standard cultures) would be an improvement on the use of less sensitive strains such as the Oxford stock Flexner V. Prima facie, it might be fancied that great sensitiveness must be an unmixed blessing, but in reality it is not so. For in bacillary dysentery sero-diagnosis depends upon the demonstration in the patient's serum of a degree of agglutination higher than that met with in normal serums. Now it is well known that normal human serums often agglutinate bacilli of the "Flexner" group. And the more sensitive the suspension used, the higher will evidently be the titre shown by such serums.

Determination of Normal Limit of Agglutination.

It is this circumstance that renders absolutely indispensable for the trustworthy use of any bacillary suspension in serodiagnosis the determination of the *normal limit of agglutination with that particular suspension.* This can only be done in one of two ways: (*a*) by testing a large number of normal serums with the suspension itself, or (*b*) by determining the sensitiveness of the suspension in comparison with another suspension which has been thus tested.

Before standardised cultures of Flexner bacilli were issued from the Standards Laboratory, a determination of the normal limit of agglutination for a suspension of the bacillus was carried out by Prof. Dreyer and myself on over a hundred normal men and a number of women in addition. Owing to the stress of war-time the results were never published. Not a single man whose past history was clear of dysentery gave a reading of as much as standard agglutination at a dilution of 1 in 50 with the suspension used. If, then, one should find a reading of this or greater magnitude given by an unknown serum, it could be taken as abnormal, and, in the absence of any other circumstance capable of raising the normal titre, diagnostic of infection.

Now all subsequent suspensions (standardised cultures) of this type of bacillus have been carefully compared with the original suspension or with one or several suspensions successively standardised, each against the previous one. To each has been given a numerical factor by which allowance can be made for its difference in sensitiveness from the original standard suspension. Thus, if a particular suspension chanced to be three times more sensitive than the standard, it would be given a factor three times the magnitude of that of the standard. Now the number of the standard units in any serum is calculated by dividing the denominator of the dilution figure (e.g., 1/25) by the factor of the suspension used; therefore, if that factor be large, the number of units is small, and vice versa. The factor for the original suspension was so chosen that normal male serums should not contain more than 10 units (a conveniently small quantity). This factor was 3·0, and a serum which gave a reading 1/25 (standard agglutination) with it contained 8·3 units. Now if the same serum were tested with the above-mentioned suspension of three times greater agglutinability, standard agglutination would be found at a three times higher dilution—viz., at 1/75. If this suspension had not been standardised it would be impossible to tell whether this reading were or were not above the normal limit. But if the suspension had been standardised and given its proper factor—viz., 9·0—the number of units calculated would be 8·3, which is definitely below the diagnostic limit.

Test of Three Normal Serums.

Three normal human serums were tested with (*a*) Prof. Dudgeon's suspension, and (*b*) a standardised Flexner (V) culture.

Serum A with Dudgeon's suspension gave a trace of agglutination in 4½ hours (55° C.) at 1/10, the strongest concentration tested, and after a further 20 hours at room temperature it showed partial agglutination at 1/10, and traces of flocculation extending up to 1/100. The same serum with the standard culture showed no flocculation at 1/10 in 4½ hours, and in 24 hours gave readings of partial agglutination (Standard plus) at 1/10, and nothing in any higher dilution.

Serum B showed in 4½ hours with Dudgeon's antigen partial agglutination at 1/62 and strong trace at 1/125, whereas the standard culture showed only a strong trace at 1/12. After 24 hours the flocculation of Dudgeon's antigen showed little or no progress; the standard culture now showed nearly total agglutination at 1/12 and a questionable minute trace at 1/25. With both serums the flocculation of Dudgeon's antigen was very irregular, in the sense that only a minority of the organisms present appeared to undergo flocculation. With the standard culture the flocculation was of the usual type seen with specific serums.

Serum C was tested with a fresh formolised broth culture of Flexner Gallipoli and with a standard culture. The serum agglutinated the former definitely up to 1/20, but gave no trace with the latter at 1/10.

Limits of Normal Agglutination with Flexner Gallipoli Suspensions.

We see, then, that the superior sensitiveness of Flexner Gallipoli is equally evident whether specific or normal serums are used for the comparison. Quantitatively, it would seem that the difference of agglutinability is even greater with normal than with specific serums. The limit of normal agglutination with Flexner Gallipoli suspensions is therefore somewhere between twice and ten times higher than with the standard culture. Clearly it is impossible to draw any conclusions as to the diagnostic value of the two types of culture without paying careful consideration to these limits.

There is no mention in Dawson and Moodie's paper of this consideration. The writers give a chart of the "agglutination-titre" at various periods of the disease. It appears to be a composite chart, but the system upon which it was compounded is not very clear to me. They state that the first trace of agglutinins (with Oxford standard culture) appeared at the end of the sixth week, but since the chart shows a curve rising from the first day they must mean something else—e.g., that they failed until the sixth week to find agglutinins above the diagnostic limit (somewhere about 1/50). Adopting the same baseline for the two suspensions, they quite naturally found the first appearance of agglutinins at an earlier date with the culture of higher sensitiveness. It is not in place here to discuss the remarkably late appearance of the agglutinins in this series of tests. Other workers with standard cultures on ordinary bacillary dysentery have reported the regular appearance of diagnostic agglutination within the first week (even on the third day of the disease), and the occurrence of the maximum commonly in the third week. A similar statement is made by Shaw Bolton and Nabarro,[1] as quoted in the paper under discussion. The most probable explanation of Dawson and Moodie's tion occurred, and several pieces of catgut and one of silk were discharged from the wound, but the patient made an excellent recovery. The aneurysm became quite hard. He had also ligatured the right subclavian and common carotid arteries for aorta aneurysm causing pressure on the trachea. The patient was relieved.

---

[1] Report of Board of Control, 1919 and 1920, vols. vi. and vii., appendix.

The PRESIDENT inquired why Sir Charles Ballance used kangaroo tendon.—Sir CHARLES BALLANCE replied that he had found that kangaroo tendon remained unabsorbed for 80–90 days, a period which could not be obtained by any method of preparing catgut.

Sir G. LENTHAL CHEATLE described

A New Operation for Inguinal Hernia.

Several cases in quick succession presenting difficulties in the efficient excision of the sac had led him to devise a new method by which these and other troubles could be easily and successfully dealt with when they arose. He approached and reached the back of the inguinal canal from a middle-line incision in the lowest part of the abdominal wall. Unless compelled by some complication he did not open the general peritoneal cavity, all the work being done in a space made in the subperitoneal tissue. He had operated in this way upon 41 patients. In the first nine all the incisions were longitudinal; in the remainder he had traversed the abdominal walls by Pfannenstiel's method.

The patient was placed in the Trendelenberg position and the operator stood on the side opposite the hernia. A transverse skin incision 4 or 5 inches long was made 1¼ inches above the symphysis pubis, with its centre in the middle line. A similar incision was made in the aponeurosis of the rectus abdominis of both sides, care being taken not to injure either *linea semilunaris*. The *linea alba* was undercut upwards and downwards to within one or two inches of the umbilicus and to the symphysis; in doing so the sheath of each pyramidalis muscle would be opened. The opening thus made in the aponeurosis was retracted up and down, and the subperitoneal tissue exposed by separating the abdominal muscles in the middle line. The peritoneum and its contents were then pushed up on both sides, and, if necessary, kept up by packing. Two retractors were inserted on the side of operation. The retractors should have long, separate and blunt prongs. The lower retractor, by far the most important instrument in the operation, should pull the abdominal wall downwards, outwards, and forwards to lift up the abdominal wall. Its prongs should reach the deep epigastric artery and vein. Nobody should proceed with the operation until he was satisfied that this retractor was in its proper position. The upper retractor pulled the structures outwards. After more completely pushing upwards the outer part of the peritoneum and thoroughly exposing the iliac fascia it would be possible to see the neck of the sac entering the inguinal canal. The deep epigastric artery and vein were then delimited and separated from the inner part of the neck of the sac. Cheyne's dissector was a very useful instrument to use for this purpose. The spermatic veins and vas deferens with its vessels were found and separated from the whole length of the exposed sac. These structures were usually on the outer and under surface of the sac. The sac having been cleared it was pulled out of the canal by gentle continuous traction in the direction in which it lay. If there were no indications of the possibility of its easy extraction the sac was cut and the canal portion replaced. (Congenital herniæ would belong to this type.) The neck of the sac, including part of the parietal peritoneum, was then transfixed and removed. Finally the inguinal canal of the opposite side was examined, and if abnormalities existed they were treated on the same lines. He had only once had to ligature a vessel in the subperitoneal space, and that was a small branch of the deep epigastric vein.

Sir G. Lenthal Cheatle then described the complications and structures with which he had met, the herniæ he would avoid, and the herniæ he would select for this operation. He had found and removed unsuspected and potential hernial sacs from the opposite side in three patients. In others he had cleared from the internal opening of the canal firmly attached dimples of the parietal peritoneum. In others he had removed fibrous cords that passed from the parietal peritoneum into the canals. In one patient the urinary bladder occupied the canal and was practically a part of the neck of the sac. The peritoneum was peeled from the bladder and the sac was radically excised. When he met this complication again he would distend the bladder with fluid. This would render the separation of the peritoneum safer and easier. In seven cases he found the urachus which bore the same relation to the sac as the bladder. The urachus was traced to its union with the bladder; it contained a good deal of unstriated muscle, very tortuous patent arteries, and some fat. In a few patients he had traced adhesions between bowel and sac, and omentum and sac into the general peritoneal cavity which he had been compelled to open to clear them satisfactorily away. The herniæ in these instances appeared to be reducible before operation. The obliterated hypogastric artery was recognised in the sac in three cases. In one of these the lumen of the vessel was not obliterated at the point of section. Sir G. Lenthal Cheatle said that from one patient he removed a small sac entering the canal, and missed a much larger one that was plastered against the iliac fascia and outer part of the inguinal opening. It was this mistake that made it so essential to expose the iliac fascia. In another patient he had the following unfortunate experience. He had removed the sac on the left side and found an unsuspected sac entering the internal ring on right side. He congratulated himself on removing these two sacs from the same opening. In six weeks the patient returned with a direct hernia on the right side. Rightly or wrongly, he associated his operation with this new hernia, and determined to take Mr. Victor Bonney's advice and adopt Pfannenstiel's method of traversing the abdominal wall. The herniæ he would *not* select for this operation were direct hernia, irreducible enteroceles, hernia in male children under 7 or 8 years, and old herniæ in which the opening has been dragged down opposite the external ring. The herniæ he would select were those in females of any age, and all uncomplicated inguinal herniæ in males over 7 or 8. He would not exclude irreducible epiploceles. He had approached femoral herniæ by the same method, but the cases were too recent to be quoted as successes as yet.

Mr. MCADAM ECCLES inquired whether the patient should be regarded as cured by mere excision of the sac.—Mr. PHILIP TURNER said that he considered excision of the sac cured almost all herniæ, with only a few rare exceptions. In his practice he now restricted the operation to excision of the sac, except in cases of obvious weakness of the abdominal wall. This he had been led to do by the success of that operation in children, and he now considered it equally successful in adults. Sir G. Lenthal Cheatle's operation had the great advantage of rendering both inguinal regions accessible, and he intended to give the procedure a trial at the earliest opportunity.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.

THE ordinary quarterly meeting of this Association was held at the rooms of the Medical Society, London, on Nov. 22nd under the presidency of Dr. C. HUBERT BOND.

Dr. BEDFORD PIERCE, the chairman of the committee who have been revising the Handbook on Mental Nursing, presented to the meeting the revised handbook, setting out the improvements which had been effected. The cordial thanks of the meeting were accorded to the committee for their labours.

Dr. M. HAMBLIN SMITH, medical officer, H.M. Prison, Birmingham, read a paper on

The Medical Examination of Delinquents.

He said that John Howard's book on prisons in the eighteenth century showed that the medical side of prison administration was, at that date, practically observers who concentrated their attention on local lesions. Of much more interest is *the unlooked-for* amelioration in all the symptoms and the long period of time over which the improvement has been maintained. Remissions for a dozen years or longer have been reported, but I have failed to trace any instance in which a case so apparently desperate achieved what may at present pass for almost complete recovery and natural arrest of the disease.

West Ayton, Yorks.

PARA-URETHRAL GONORRHŒA.

BY F. CHAMBERLAIN, M.R.C.S., L.R.C.P. LOND.,
HOUSE SURGEON TO THE LONDON LOCK HOSPITAL.

A para- or accessory urethra is a small blind canal lying somewhere between the meatus urinarius and the penile-scrotal junction in the long axis of the penis. The canal opens at the distal end but is closed at the proximal end and does not communicate with the urethra proper. The lining is of epithelial cells supported by connective tissue, indistinguishable in form and arrangement from those lining the urethra, a small bore urethra in effect. In most cases the urethra is of narrow calibre and one gains the impression that the condition is due to a developmental error whereby a portion of the urethral track is cut *off from the main urethra.*

In certain cases these canals may become infected with gonococci, the urethra proper escaping. I hazard the theory that the cause is largely mechanical. In Case 1 the extreme phimosis must to some extent have protected the meatus urinarius, while the opening of the canal on the under surface of the prepuce *would bear the brunt of the onslaught* during coitus. In Case 2 the three openings were close together, but the meatus was very narrow, hardly admitting an 11 F. bougie, and the lips were indrawn, presenting the resistant skin surface of the penis instead of the delicate lining of the urethra. Distension of the glans during erection rendered the para-urethral openings more prominent.

CASE 1.—Aged 23, no previous venereal disease. Marked phimosis; had never been able to retract foreskin. Narrow meatus; an ovoid swelling, 12 by 6 mm., on the under surface of the penis with pus exuding from four openings. A fine probe passed through the distal opening demonstrated a canal 3 cm. in length lying superficially in the raphé. Pus contained gonococci. Urine was limpid and contained no flakes.

Treatment.—The canal was dissected out and the edges sutured. Healed by first intention. Three months later a faint scar was discernible; there had been no signs of urethral gonorrhœa.

CASE 2.—Aged 23, no previous venereal disease. Three days after coitus noticed a "boil" on the glans. This was treated with foments and later with various ointments till another boil arose and the end of the penis became impetiginised. On examination a pocket 3 mm. in depth was found, and proximal to this a canal 3½ cm. in length, *starting 6 mm. from the meatus* and passing from the glans, through the frenal fold, and on to the prepuce to the skin-mucus junction.

Treatment.—The septum between the pocket and the canal was perforated and the whole track laid open with a pair of iridectomy scissors and packed with acriflavine gauze; the wound healed, leaving a ribbon-like track. Two months later the track was hardly distinguishable from the rest of the penis. There had been no signs of urethral gonorrhœa; gonococci were found in the original discharge from the canal.

CASE 3.—Mr. J. E. R. McDonagh has given me permission to include a case in which the track extended almost the whole length of the raphé and the pent-up pus had made its way to the surface by several openings. Gonococci were found in the pus; no signs of urethritis then or since. The track was dissected out and the wound sewn up. No trouble since.

It is important to recognise that these ducts can be infected without any signs of "gonorrhœa," as, by the time the patient has maltreated his penis with irritating ointments to cure his "sore," the original lesion will be quite unrecognisable, and there is *no urethral discharge to give one a lead.* Hot dressings and ointments will then be of no avail.

I am indebted to Mr. McDonagh and Mr. Johnston Abraham for permission to publish these cases.

A FATAL CASE OF
DELAYED NEO-SALVARSAN POISONING.

BY D. R. C. SHEPHERD, M.B., M.R.C.P. LOND.,
TEMP. CAPTAIN, R.A.M.C.; MEDICAL SPECIALIST,
ALDERSHOT COMMAND.

DEATH due to the means of cure of syphilis is by no means rare, but in the case here recorded death occurred 111 days after the last of seven injections of neo-salvarsan.

J. G., a soldier, aged 21, commenced treatment on Sept. 9th, 1920, after the *Spirochæta pallida* had been found in his primary sore. The following is an extract from his case sheet showing the dosage employed:—

Connaught Hospital, Aldershot.

10/9/20	914	0·4 g.	Hg. gr. 1.
17/9/20	914	0·4 g.	Hg. gr. 1.
21/9/20	914	0·4 g.	Hg. gr. 1.
1/10/20	—	—	Hg. gr. 1.
8/10/20	914	0·6 g.	Hg. gr. 1.
15/10/20	914	0·6 g.	Hg. gr. 1.

Rochester Row.

29/10/20	914	0·6 g.	Hg. gr. 1.
5/11/20	914	0·6 g.	Hg. gr. 1.

He reported sick with jaundice, but no other symptoms on Feb. 6th, 1921, and was admitted to the Cambridge Hospital, Aldershot, on that day. So-called catarrhal jaundice is common in the command, and his case presented no peculiarity until the 22nd, when he became depressed and refused food; vomiting set in, the jaundice deepened, and he died comatose in 36 hours. The urine on the day of death contained albumin, blood, and bile-stained granular casts. It showed the presence of arsenic by Marsh's test. Leucin and tyrosin were absent. Post mortem, the liver weighed 30¼ oz., *and showed the typical appearance of* acute yellow atrophy both macroscopically and microscopically. The kidneys showed acute diffuse nephritis and there was some venous congestion of the spleen. The other organs were apparently healthy. No spirochætes were found in films of juice from liver and kidney.

Analysis by Major Elliot, B.Sc., F.C.S., gave the following result:—

	Weight in grammes.	As. per 100 g.
Kidneys	391	0·02 mg.
Liver	832	0·1 mg.
Spleen	241	0·2 mg.
Bone	19	0·2 mg.

Mr. A. G. R. Foulerton tells me that the relative amounts (if the liver and kidneys are considered together) agree closely with his findings in experimental As_2O_3 poisoning. A rough estimate shows that probably nearly one-tenth of the total arsenic administered remained in the body at death. The elimination of *arsenic from organic combinations is, I find, a longer* process than is usually believed. Three patients free from symptoms were found recently to have arsenic in the urine in demonstrable quantity 11 weeks after their last injection of neo-salvarsan.

I have not been able to find any other record of analysis of the arsenic concentration in so remote a fatality as the above, for permission to publish the details of which I am indebted to Lieut.-Col. H. C. R. Hine, commanding the Cambridge Hospital.

MEDICAL GOLFING SOCIETY.—This society has been carried on in a more or less informal manner for 23 years, but it has now been decided to put it on a business footing. Two tournament meetings are to be held annually, and team matches and other competitions for four cups, *including two challenge cups, will be arranged.* Membership, without election, is open to any gentleman on the Medical Register, on payment of the annual subscription of 10s. to the hon. secretary and treasurer, Dr. Rolf Creasy, jun., 30, Weymouth-street, London, W. 1.

methods enabled a better adjustment to be made. To achieve this Freud employed the method of free association. Dr. Davies Jones quoted cases to illustrate his thesis.

The paper was discussed by Dr. James Stewart, Dr. C. Stanford Read, Dr. Bedford Pierce, and Dr. A. E. Evans, and Dr. Davies Jones replied.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

A meeting of this Society was held at the West London Hospital on Dec. 2nd, Sir G. Lenthal Cheatle, the President, being in the chair, when a discussion on

The Treatment of Puerperal Infection

was opened by Dr. Frederic J. McCann. He compared the nature of puerperal infection with that of ordinary septic wounds. The normal sequence of events in a healthy puerperium was attained chiefly by the increased vascular and lymphatic supply of the involuting uterus. Dr. McCann emphasised the importance of wounds of the cervix, vagina, and vulva as sources of infection, and criticised the orthodox teaching that infection usually originated within the uterus. After alluding to the modes of spread and the general course of the infection, he proceeded to discuss the importance of prophylactic measures. He deplored that our hospital system provided such scanty accommodation for puerperal cases. The teaching of obstetrics also should be improved. Medical officers of health should be empowered to admit to hospital women whose domestic surroundings were unsuitable for a confinement. The application of forceps and the introduction of the hand into the uterus should be regarded as major operations. Rectal examination should be avoided; its disadvantages were obvious. Vaginal and perineal wounds and deep cervical tears should be carefully cleansed and sutured. With regard to the treatment of infected cases, in the first place extra-genital sources of infection must be excluded. Exploration of the uterus was only permissible in the severer types of cases or after any likely source of infection in the lower genital tract had been excluded. The curette should be used as a probe only or for gently removing any loose fragments, and never as a scraper. Puerperal peritonitis and localised abscesses must be dealt with on ordinary surgical lines. Subcutaneous salines, free purgation, and the judicious use of quinine were all valuable. Serum and vaccine were, on the whole, disappointing.

Discussion.

The President warned practitioners against placing too much reliance on the alleged antiseptic properties of many gauzes on the market.—Dr. Remington Hobbs was strongly in favour of uterine drainage, as, in his opinion, the rise of temperature was due to mechanical blocking of the uterine outlet by malpositions of the uterus, œdema of the cervix, and overloading of the rectum. For this purpose he used a small rubber catheter. After cleansing the genital passages the catheter was introduced into the uterus by means of a special forceps made to his design. 10 c.cm. of a glycerine and iodine mixture (in the proportions of 7 to 1) were then injected into the uterus. It might be necessary to repeat this injection on several consecutive days according to the course the temperature took. He showed a series of temperature charts which appeared to bear out the efficacy of this line of treatment.—Dr. H. J. F. Simson referred to the importance of prophylaxis, and wondered to what extent the glycerine was responsible for the success of Dr. Hobbs's treatment.—Dr. Knyvett Gordon stated that an experience of 250 cases had led him to believe that the best line of treatment was curettage, saline infusions, and the use of anti-sera (according to the bacteriology) in large doses combined with saline. Laparotomy and even hysterectomy were indicated in the severer cases.—Dr. Bernard Spilsbury referred to the severe type of case usually seen by him; in some of these cases death occurred as early as 24 hours after infection. There was in these cases little macroscopic evidence to account for the infection.—Dr. J. Burnford laid stress on the importance of bacilluria as a cause of fever during the puerperium. Bacteriological examination of the urine should be a routine procedure in puerperal cases associated with pyrexia.

Other speakers included Mr. Malcolm Donaldson, Dr. Lapthorn Smith, Dr. Vaughan Pendred, Dr. Sanguinetti, and Dr. F. G. Lloyd.—Dr. McCann replied.

PATHOLOGICAL SOCIETY OF MANCHESTER.

A meeting of this Society was held on Nov. 9th, with Mr. J. Howson Ray, the President, in the chair.

Dr. C. P. Lapage opened a discussion on

Tuberculosis in Children.

He pointed out the frequency of tuberculous infection in children, as shown by: (1) Post-mortems at the Children's Hospital, Pendlebury. These showed the great frequency of glandular tuberculosis, in many cases without disease of the organs. They also showed that cavitation of the lungs in babies is not uncommon. (2) X ray examinations to demonstrate thoracic tuberculosis. (3) The results of the Von Pirquet skin reaction in 1000 children, as demonstrating the incidence of non-fatal tuberculosis in the age-periods of childhood. (2) and (3) were correlated to the clinical examination and the close correspondence between the three methods of examination pointed to the fact that tuberculosis in its early stages should be recognised by symptoms and history rather than by physical signs. One thousand cases were divided clinically in five categories—i.e., negative, possible, suspicious, probable, and positive. Even the suspicious cases had no physical signs, but only pallor and debility, some loss of flesh and an indefinite cough, in some cases with a history of infection in the home. These were often tuberculous and when tested with the Pirquet test at the different age-periods, gave results as follows: 0–2, 5 per cent.; 2–5, 62 per cent.; 5–10, 67 per cent.; 10–14, 59 per cent. Dr. Lapage discussed the frequency of tuberculosis and its variability in different areas in relation to the milk-supply, and concluded that, though infection from human sources is much the more common and more dangerous, yet the danger from tuberculous milk is a very real one, especially when the likelihood of massive doses is present. The autopsies seemed to show that the tubercle bacillus could pass through the damaged mucous membrane and clinically this seems possible, especially if some illness such as chronic enteritis or bronchitis lowers the health of the child and produces local inflammation and perhaps stagnation. Closed or open disease results. In some cases there is a marked bacillæmia resulting in generalised tuberculosis. In others, tubercle bacilli are disseminated to various parts of the system where they may remain latent; then at some subsequent period of lowered health with perhaps local injury, they may be lighted up and form isolated areas of disease, such as nodules, or joint or bone trouble. The mode of spread is, however, more often by the lymphatic system. Tuberculosis was a very fatal disease, especially in young children, the death-rate falling very rapidly after the second year—i.e., 25 at 0–1 year, rising to 40 at 1–2 years, and falling to 20 at 2–3 years. A great deal of non-fatal tuberculosis occurred, but Dr. Lapage said that every effort should be made to postpone infection as late as possible on account of the very high death-rate at the early age.

Mr. E. D. Telford discussed the subject from the surgical aspect. His figure for bovine infection in Manchester was 50 per cent., the route of infection being as a rule via the digestive tract. The average age of clinical onset in a large series was 3½ years,

ROYAL SOCIETY OF MEDICINE.

SECTION OF SURGERY.

A meeting of this section of the Royal Society of Medicine was held on Dec. 7th, Mr. Raymond Johnson, the President, being in the chair.

Sir Charles Ballance read a paper on

Ligation of the Innominate Artery for Innominate Aneurysm.

Four of his own cases were described.

Case 1.—Female, aged 60 years, who had had syphilis. She had deformed tibia and an old iritis. There was a pulsating expansile tumour rising from the superior mediastinum above the inner extremity of the right clavicle and the suprasternal notch. Radiographic examination showed that the aneurysm was limited to the upper portion of the innominate artery. The pulses in the right arm and right carotid were markedly weakened. As there appeared to be a portion of the innominate artery not implicated in the aneurysm, it was decided to explore the mediastinum, and tie the proximal portion of the artery. This was done on Dec. 31st, 1918. The aneurysm was reached through a median vertical incision, in the lower part of the neck, with a transverse incision across the upper part of the sternum. The muscles were detached from the inner part of the left clavicle and the left portion of the manubrium, and the inner extremity of the left clavicle, together with the left upper portion of the manubrium, were removed. The pleura was pressed away and the upper part of the arch of the aorta found by dissection in the fibro-fatty tissues of the mediastinum. The proximal unexpanded portion of the innominate artery was then easily traced and ligatured with two strands of kangaroo tendon tied in a stay-knot, without rupturing the inner coat. Pulsation in the aneurysm ceased at once. The wound healed by first intention, and in six weeks' time the aneurysm had shrunk much in size and become solid. The right arm was troublesome at first, being cold and painful, but improved slightly, although pulsation could not be detected in any vessel. In January, 1921, the right arm had completely recovered, the two radial pulses being equal. A large vessel felt crossing the right posterior triangle of the neck was thought to be possibly an enlarged transversalis colli artery. In May, 1921, the patient was readmitted to St. Thomas's Hospital with severe albuminuria, ascites, and œdema with cardiac complications. She died on June 6th, 1921. The autopsy revealed a large infarct in the lung, which was the immediate cause of death. The large vessels at the root of the neck were dissected out and distended under pressure. Sir Charles Ballance showed the specimen; the artery was obstructed at the site of ligature, the aneurysm had disappeared, its remains being a mere fibrous mass. The greater part of the right subclavian artery was patent, and circulation had apparently been re-established through the branches of the first part of that vessel. The transversalis colli was not enlarged as had been supposed.

Case 2 was reported fully in The Lancet, 1902, II., p. 1180. Sir Charles Ballance recalled its salient features. The patient was a man, aged 35 years. The aneurysm involved the bifurcation of the innominate artery and extended some distance into the right side of the neck. The patient had previously undergone a course of Valsalvian treatment. The proximal portion of the innominate artery was exposed on this occasion by dividing the manubrium vertically in the middle line, and transversely at the level of the upper border of the second costal cartilage. This portion was tied with four ligatures of goldbeater's skin tied in two stay-knots. The patient died 30 hours later, after exhibiting signs of a left hemiplegia. At the autopsy the great vessels were removed and preserved. The right common carotid, internal carotid, and middle cerebral arteries were found full of clot.

Case 3 (a case previously reported in 1912 to the Clinical Section of the Royal Society of Medicine).—In a clerk, aged 43 years, the aneurysm involved all three parts of the right subclavian artery. Sédillot's operation was attempted, but abandoned on discovering the nature and extent of the aneurysm. The upper portion of the manubrium was then removed and the innominate artery exposed and tied in a stay-knot with kangaroo tendon. Pulsation in the aneurysm ceased at once. The right arm was very little affected and the tumour slowly decreased in size. The patient could, unfortunately, not be traced subsequently.

Case 4.—A man, aged 35 years, who had had syphilis seven years before, seen in 1909 on account of a large and increasing pulsating swelling in the right side of the neck, diagnosed as aneurysm of the bifurcation of the innominate. As the condition was progressing in spite of rest in bed, it was decided to operate. A portion of the manubrium was removed, together with portions of the left first and second costal cartilages, and the proximal portion of the innominate artery exposed. As the ligature was about to be passed the aneurysm, which was being pushed aside by the fingers, ruptured. Sir Charles Ballance controlled the hæmorrhage by passing his fingers into the aneurysm and plugging the innominate, and the vessel was tied with kangaroo tendon and a stay-knot. The patient died 30 hours later, and the specimen was not obtained.

Surgical Aneurysm of the Innominate.

Sir Charles Ballance showed a specimen (No. 1507) from St. Bartholomew's Museum as typical of surgical aneurysm of the innominate—i.e., one involving the bifurcation of the artery whilst the proximal portion remained unexpanded and available for ligature. Anatomically speaking, ligation of the innominate artery should be a cervical operation, but from a practical point of view it was advisable to remove bone so as to obtain a clear and free exposure of the parts. The amount of bone to be removed varied with different cases. He had found the operation not very difficult, although he would not go so far as the late Sir W. Mitchell Banks in describing it as a "mere surgical amusement." In 1915 Thomson ("Annals of Surgery," vol. lxi.) had collected 52 cases of ligation of the innominate for subclavian aneurysm with 16 recoveries (30·7 per cent.), and five further cases had since been reported, with two deaths, whilst in one of the non-fatal cases pulsation reappeared in the aneurysm in three weeks. Sir Charles Ballance wished particularly to emphasise the following points:—

1. That cases about to be submitted to operation should not be previously treated by the method of Valsalva.
2. That there was a group of cases of aneurysm of the innominate artery (aneurysm of the bifurcation) which were suitable for proximal ligature. Distal ligature caused the aneurysm to become a diverticulum of the aorta and so increased the pressure within it, and should not be done when proximal ligature was possible.
3. That the presence of the aneurysm necessitated removal of a part of the manubrium in order to gain a free and clear exposure of the vessel below the aneurysm.
4. That the ligation of the innominate might be safely and surely accomplished if the ligatures were tied in a stay-knot without rupturing the coats.

Sir Charles Ballance added that the tension in the wall of a vessel varied with the size, thus explaining the prevalence of aneurysm in the aorta and other large vessels. The tension in the large vessels was much greater than could be explained merely on the grounds of the higher blood pressure in them. When a fusiform dilatation occurred the tension in the wall of the vessel was still further increased, thus explaining the tendency of aneurysmal swellings to progress. The same factor occurred in steam pipes, and lack of recognition of the influence of the size of the vessel on the tension within it frequently led to bursting of the larger boilers in the early days of steam power.

Discussion.

Sir Charters Symonds said he also had ligatured the innominate artery. The case had not been published, although a brief account of it could be found in Jacobson's "Operations of Surgery." The case was one of aneurysm of the second and third parts of the subclavian. The first part of the vessel was exposed by a cervical incision and two attempts made to ligature it, both of which caused severe hæmorrhage. He then decided to ligature the innominate artery, which he was able to do from the neck without removal of bone by making gentle traction on the common carotid artery. Mild suppura-

Reviews and Notices of Books.

PULMONARY TUBERCULOSIS.

By Sir JAMES KINGSTON FOWLER, K.C.V.O., C.M.G., M.D., F.R.C.P., Consulting Physician to Middlesex Hospital, Hospital for Consumption and Diseases of the Chest (Brompton), King Edward VII. Sanatorium, Midhurst. London: Macmillan and Co. 1921. With 52 illustrations. Pp. 284. 20*s*.

MANY features distinguish this book from other treatises. For example, Sir James Kingston Fowler breaks away from the beaten track in his historical survey, giving prominence to two British workers—William Stark and William Budd—whose contributions to the advancement of medical science have hitherto been underrated. It is a pity that his appreciation of these and other British scientists should have as a setting a sweeping denunciation of German scientists in a spirit reminiscent of war-time propaganda; though Koch and Walther do exceptionally receive praise. A short but most interesting chapter on the Rôle of Heredity ends with the rather unexpected conclusion that the attempt to state with scientific precision the influence of heredity is doomed to failure. This is not a satisfying verdict, but the author justifies it with many cogent arguments proving the intricacy of the problem. In this, as in practically every chapter, he shows a first-rate and first-hand knowledge of morbid anatomy.

A characteristic and eupeptic feature of this book is the author's tendency to lapse into a conversational style marked by quips and barbed digs at the foibles of faddists, though some of his criticisms are ill-advised. His scepticism as to the very existence of such a morbid entity as "hilum tuberculosis" finds expression in his definition of it as "a 'shadow' first seen in a darkened room and not yet clearly recognised in the daylight of the post-mortem room." To which the sponsors of "hilum tuberculosis" might feel tempted to retort by quoting the author's opinion expressed elsewhere in this volume that one does not find a condition post mortem till one looks for it. Another and most valuable characteristic of the book is the imposing quantity of clinical experience and sound advice it contains. In a few lines Sir James Kingston Fowler tells more about hydrotherapy, the ominous significance of the inverse type of fever, the curability of tuberculous meningitis, the folly of exploring for fluid with a fine needle, than most writers can condense into several pages. Here and there his advice seems hardly up to date; in discussing the treatment of accidental pneumothorax he omits all reference to oxygen or nitrogen replacement. In some cases it may be advisable to exploit an accidental pneumothorax and to maintain it as an artificial pneumothorax by injections of gas. His opinion of modern methods of diagnosis is seldom flattering. Force is given to a depreciatory discussion of X rays by a reference to the author's own experience during the war at a military hospital, where, in collaboration with the late Mr. C. R. Lyster, he was able to check this method with that of ordinary physical examination.

The author is a caustic critic of the use of tuberculin, and he suggests that "a tuberculosis dispensary that has become a 'tuberculin' dispensary has become a very dangerous place." "Artificial pneumothorax," he says, "is the only advance in the treatment of pulmonary tuberculosis since the introduction of sanatorium treatment as carried out at Nordrach." He is a supporter of sanatorium treatment, but is rather difficult to follow in discussing the vexed question of graduated exercise. On page 220 he writes: "No exercise, except walking, for two years, i.e., after the arrest of the disease and disappearance of tubercle bacilli from the sputum"; while on page 232 he speaks with evident enthusiasm of the excavation by Frimley patients of 5000 tons of earth wheeled 300 yards.

The dominant virtues of this book are its sound pathology and ripe clinical experience: they are in evidence on almost every page. Its failing is that of its limits. Instead of giving space to a full account of such an epoch-making advance as, for example, the Pirquet test, the author often digresses to quote earlier writings and to show how views expressed many years ago have now been proved correct. The book, therefore, is hardly suitable for the student actuated by the single-hearted desire to please examiners, but it is a work which both general practitioners and tuberculosis specialists will enjoy reading.

DIAGNOSIS AND TREATMENT OF VENEREAL DISEASES IN GENERAL PRACTICE.

Third edition. By Brev.-Col. L. W. HARRISON, D.S.O., M.B., Ch.B., M.R.C.P.E., Director of Venereal Department, St. Thomas's Hospital. With a chapter on the Medico-Legal Aspects, &c., by F. G. CROOKSHANK, M.B., F.R.C.P. London: Henry Frowde and Hodder and Stoughton. 1921. Pp. 525. 25*s*.

THE first edition of this book, published in 1918, rapidly won its place as the authoritative English text-book on the subject, and it is not surprising that a third edition has been called for so soon. It has certain conspicuous merits. It is well arranged, covers the ground adequately, is thoroughly up-to-date; it is remarkably free from redundancies, and while its teaching is dogmatic whenever necessary, on matters as to which there is still considerable divergence of opinion the author preserves balance. Further, he deals with every aspect of the subject so systematically, and in such detail, that it is an invaluable guide for the tyro, while the expert will find much that is stimulating and suggestive in its pages.

One slight shortcoming of the earlier editions has been remedied: the treatment of gonorrhœa in the female is now dealt with in full detail. Further, a valuable section has been added on "proofs of cure" in gonorrhœa. This should be of great help to those who are anxious not to stop treatment too soon, and at the same time should serve to protect patients from over-treatment. Like many other workers in the same field the author has found that success in the treatment of gonorrhœa with vaccines depends on (1) proper dosage, (2) the strain of gonococcus employed, and (3) the method of preparation of the vaccine. His review of vaccine treatment, which includes observations on patients treated with detoxicated vaccines, is concise but valuable, and his conclusion, with which most workers will agree, is that the case of gonorrhœa subjected to a rational vaccine-therapy runs a milder course than that from which vaccines are withheld.

In the section on the treatment of syphilis considerable modifications have been introduced since neo-salvarsan or one of its congeners is now generally used in place of "606." All the arsenical derivatives of use in the treatment of lues are passed under review, including silver-salvarsan, and a useful series of tables, based on the routine courses of treatment in use at St. Thomas's Hospital, is inserted. In these tables the equivalent doses of 914, 606, and silver-salvarsan are tabulated, and any patient treated upon the lines there laid down will not suffer from inadequacy of treatment. Colonel Harrison's experience has led him to doubt the anti-syphilitic powers of mercury, and he emphasises the need of combined administration of arsenic and mercury in the "continuation treatment" of the disease. The chapter on the prevention of venereal diseases gives much food for thought. After reviewing the subject, and giving statistical tables based on the experience of the U.S. Army in France, Colonel Harrison concludes that "the greatest hope lies in the prompt treatment of patients in the earliest stages of the disease, thereby ensuring a maximum of cures and a minimum of infection carriers."

non-existent. Though many of the prisons had a surgeon attached to them, he seemed to have come in only when specially required. For many years past, however, every prison had had a regular M.O. as part of the establishment, and his duties and functions had undergone remarkable developments. Our larger prisons were well built and well equipped, and the nursing staff had altered for the better. The M.O. had opportunities, especially in the case of long-term prisoners, of observing the effects of diet and work, as well as watching the development of various forms of disease. Dr. Smith said that various physical ailments conduced to delinquency, in so far as they affected the mental life. For example, a man suffering from such a physical defect as hernia, tuberculosis, or defective vision, was handicapped in earning his living in the competitive labour market, and hence was more likely to break the law. Those physically defective from cardiac or phthisical disease were unable to work regularly, and thus did not form, early in life, good habits of industry; moreover, the physically weak child was often kept away from school and thus not only formed bad habits early, but received more than the usual sympathy. A boy with defective vision would be a constant trouble to his teachers, who, ignorant of the defect, would punish undeservedly, producing in the child a mental conflict which might result in delinquency. This contingency was now largely prevented by the present system of school inspection. Moreover, the tendency of certain physical disabilities was to make their victims anti-social, owing to the feeling that they were not as others. The duties of the prison doctor soon grew beyond the mere treatment of physical ills; no uniformity could be carried out in the way of diet, work, and disciplinary punishment, and the doctor was constantly being called upon to exercise discretion.

There had been a great development, too, in the mental side of his work. Probably this was originally confined to certification of cases of legal insanity; prisoners were held to be either normal or insane, in a rigid sense. But a man, though not insane, might have a mentality differing from that of the strictly normal person, and these abnormal cases were now placed under the medical officer's direct charge, and could now be certified under the Mental Deficiency Act, 1913. No rigid division between normal and insane prisoners was possible; every offender presented an individual problem. Public opinion was probably not yet ripe for universal investigation of individual cases, though the courts and the public should be educated up to the need thereof. Dr. Smith said he had devoted much time to the selection and application of a scheme of tests. His earlier work was done with the Binet scale, but he became dissatisfied with that scheme, and moreover was not satisfied as to the propriety of the fashion of considering "mental age." He was dealing with the test he now used in a book shortly to be published. Much light had been shed on problems of delinquency by the so-called new psychology. He was not saying that there was always a mental conflict at the root of delinquency, or whether such conflicts were always of a sex character. But he felt certain that such a conflict was present in many cases, and the discovery of this might alter the whole aspect from which the particular offender was regarded. He thought a scheme would need to be devised for the placing of suitable cases under the care of official psycho-analysts. At Birmingham the prison doctor was an integral part of the city's scheme for dealing with its delinquents. Dr. W. A. Potts had been appointed to examine cases which it was not desired to send to the remand part of the prison. The male and female remand departments were arranged and worked, as far as possible, on hospital lines, the idea of prison being kept out of sight. Dr. Smith proceeded to describe the routine followed. It was now very rare to get a mental defective or a psychosis case from the city of Birmingham on conviction. He advocated a division of the country into convenient districts, each having a properly equipped prison with a special M.O. in charge, to which all cases requiring mental examination should be sent. The only alternative plan would be to have travelling mental examiners in each district, who could attend when required. His conclusion was, that uninvestigated offenders were the most expensive luxury that any community could indulge in. He thought there should be a closer union between the prison and asylum services; there might be a unified service, working in each district under a local head, who would be the director and inspirer of the work. Dr. Smith then detailed the requirements which psychiatrists for this work should possess, and referred to the intention of the University of Birmingham to hold, next summer, an intensive course of lecture-demonstrations. He alluded, in conclusion, to the valuable work of the school medical officer.

Discussion.

Dr. W. A. POTTS confirmed Dr. Smith's opinion that every offender was worthy of investigation, and that this would prove in the end an economical procedure. He alluded to the importance, in doubtful cases, of an examination before the supposed offender was sent to prison, in order to preserve his self-respect.

Dr. J. T. DUNSTON (Commissioner of Mentally Disordered and Defective Persons of South Africa) spoke of a recent visit to New York State. There each person sentenced to imprisonment for a year or more went through a thorough medical examination. A beautifully-fitted reception prison was being built, and next to it a large medical institute, under the stimulus of the National Committee for Mental Hygiene. So far, the work had been done, under some difficulty, by Dr. Glueck. After the medical examination each case was examined by a psychologist, who had to decide whether the prisoner was defective, or mal-adjusted, or actually insane. If normal, the man was recommended the right vocational training or treatment. Hence every felon's fate was decided not by the magistrate, but by the examining psychiatrist. In Chicago every juvenile delinquent was examined by a psychiatrist, who sat beside the judge as assessor, and made a rapid diagnosis. In Massachusetts, however, a most detailed personality study was made. In America the prevailing view seemed to be that it was the individual who really mattered, not the crime.

Mr. A. H. TREVOR (Commissioner of the Board of Control) said it was impossible to hear what was being done in Birmingham and in America in keeping defective persons out of prison without sympathising with such efforts to the full.

Sir ROBERT ARMSTRONG-JONES spoke of an effort now being made to found a Magistrates' Association, one object of which would be to secure greater uniformity in the dealing with similar offences in the various districts.

Dr. H. DAVIES JONES read a paper on

Forgetting.

He explained that he was not attempting to deal with the complete amnesias met with in the practice of psycho-analysts. Freud claimed that forgetting, whether for words or deeds, was not a fortuitous occurrence, but that a reason could usually be revealed by psycho-analytic methods. A means of gauging the value of an amnesia was the emotional effect accompanying. Dr. Davies Jones spoke only of cases where a sufficiently deep impress had been made. Forgetting was not a passive but an active process; we forgot, because we did not wish to remember, something unpleasant because it clashed with our innate tendencies. Each time the undesired memory recurred an attempt to repress its expression was made, and eventually the repression would become a part of the unconscious self. Still, it possessed a latent energy which could not be destroyed, and expression would occur by devious routes. Psycho-analytic by past failures; witness the interesting chapters on Female Offenders, Vagrancy, and Inebriety. Perhaps he is at his best in the chapter on the Borstal System, the development of which has evidently been his special care.

A special chapter on the Medical Service describes the numerous demands on the prison doctor. We hope that all prison medical officers have the ability attributed to them by Sir Evelyn Ruggles-Brise, but it is doubtful whether a doctor who has to develop along so many different lines is always qualified, even if he has served a term as officer in an asylum, to give the best opinion on insanity and mental defect. This manual is a valuable one which can be read with interest and profit by any intelligent citizen; for the specialist it is essential. There is an excellent and correct index, and the whole production forms a setting worthy of the subject matter.

A MANUAL OF PHYSICS.

Second edition. By J. A. CROWTHER, Sc.D., F.Inst.P., Sometime Fellow of St. John's College, Cambridge, Demonstrator in Physics in the Cavendish Laboratory, Cambridge. London: Henry Frowde and Hodder and Stoughton. 1921. Pp. 537. 16s.

THE appearance of a second edition of Dr. Crowther's Manual of Physics so soon after the first is the surest evidence of the need for a work which gives, not too briefly, the outlines of elementary physics.

The book may well be popular among medical students, for the subject-matter is well arranged, the explanations of some of the more difficult parts of the subject are quite adequate, and the whole of the letterpress is interspersed with diagrams which, on the whole, leave little to be desired. In the section on Photometry we should have liked to see included Joly's elegant and simple method of comparing the illuminating powers of two sources. The reader will have some difficulty in seeing from diagram No. 125 how the observer may directly view the two illuminated surfaces. The diagram showing the minimum deviation (printed duration) is too symmetrical, and might give the reader the impression that the angle of refraction was necessarily just one-half that of the angle of incidence. The diagrams illustrate a well-written and very useful book.

DISEASES OF CHILDREN.

By HERMAN B. SHEFFIELD, M.D., formerly Instructor in Diseases of Children, New York Post-Graduate Medical School and Hospital, &c. London: Henry Kimpton. 1921. Pp. 798. 48s.

Dr. Sheffield's book contains no salient advance on the methods of diagnosis and treatment commonly recommended in this country, and will make no special appeal to English readers. Even with regard to infant feeding, the methods advocated resemble our own system of percentage feeding, with its associated disadvantage of the difficulty experienced by inexpert attendants in the preparation of the milk mixtures ordered. With Dr. Sheffield's prescriptions for diet after seven months, and indeed up to five years, we cannot agree; the diets appear complex, and insufficient in many respects, containing an unnecessary excess of fruit juice and fruit pulp and not the necessary variety of proteins. A section on the Prevention and Control of Disease, however, contains much that is of value; the method of intravenous perfusion via the anterior fontanelle into the superior longitudinal sinus is advocated for infants, and the administration of intraperitoneal saline solution in acute summer diarrhœa—a method first practised in England—is carefully described. The section devoted to the physical examination of children seems elementary and redundant. The difficult study of disease in childhood should surely follow preliminary general instruction in clinical methods, and a recapitulation of physical signs and surface markings is superfluous in a text-book devoted to this special subject.

The description on p. 268 of a case of acute intussusception in a young infant, which remained undetected for three days, reflects but little credit on the physician. It is surprising, too, that the special incidence of intussusception in breast-fed infants should have escaped the author's notice. A more hopeless confusion than exists under the heading Rheumatism and Rheumatic Fever would be difficult to imagine. This all-important disease of childhood receives scanty treatment; the description of the early physical signs of a heart damaged by rheumatic infection and of its treatment is altogether unsatisfactory.

The subject-matter of the book is, on the whole, well arranged, and the plates, mostly from photographs, are excellent, but the cumbersome use of dog-latin equivalents in the nomenclature of disease throughout the book is unfortunate. The book is attractively produced, and the colour plates are excellent.

JOURNALS.

JOURNAL OF PHYSIOLOGY. Edited by J. N. LANGLEY, Sc.D., LL.D., F.R.S. Vol. LV., Nos. 5 and 6. Cambridge University Press. 1921. Pp. 305–428. 11s.—The Regulation of the Excretion of Water by the Kidneys, by J. G. Priestley. The problem discussed is whether the diuresis following the drinking of large amounts of water is related to any changes in the blood comparable to the changes in hydrogen-ion concentration which regulate the breathing. The excretion of urine can be increased by drinking water from about 40 c.cm. per hour up to as much as 1200 c.cm. per hour, the specific gravity falling to less than 1001; the comparative estimations of the amount of hæmoglobin in the blood before and after diuresis showed no appreciable change. After water-drinking, the loss in weight on drying blood; the chlorine content of the blood; the excretion of water and chloride in the urine during water diuresis were estimated. It was proved that there were slight but definite changes in the composition of the blood accompanying the diuresis provoked by drinking water. The excretion of water is largely but not entirely in relation to the excretion of chlorides. Injection of pituitrin (1 c.cm. intramuscularly immediately or shortly after drinking two litres of water) delays the diuresis produced by water-drinking for 4–6 hours. Water diuresis then sets in and is accompanied by an increased excretion of chlorides. These results, it is suggested, are compatible with the regulation of excretion of water by the kidneys of a two-fold nature: (a) a main regulation dependent on the diffusion pressure of water in the blood, and (b) a subsidiary modification of this regulation dependent on the inability of the kidney to hold back water when the diffusion pressure of water in the urine is considerably below that of the blood.—The Identity of Hæmoglobin in Human Beings, by G. S. Adair, J. Barcroft, and A. V. Bock. The different affinities for oxygen of various samples of human blood may be due either (1) to differences in the hæmoglobin itself, or (2) to differences in the conditions affecting it—e.g., the salt and hydrogen-ion concentration. It would seem that if samples of hæmoglobin from different individuals be freed from the corpuscles in which they are held and be subsequently treated in exactly the same way, they give oxygen-dissociation curves which are indistinguishable. On the other hand, preparations prepared by slow dialysis of blood against distilled water may simulate solutions in appearance but still containing intact, though swollen corpuscles, give dissociation curves far different from those of true aqueous solutions of hæmoglobin.—The Direct Measurement of the Partial Pressure of Oxygen in Human Blood, by J. Barcroft and M. Nagahashi. In principle the method used was to withdraw blood from a vessel, artery, or vein by direct puncture. To this blood is exposed a small bubble of alveolar air at 37° C. until an equilibrium is established between the blood and the bubble. The bubble is then analysed in a suitable apparatus. The from which he deduced a fairly long latent period after the original infection. In younger infants tuberculosis tended to be more acute and more generalised. Mr. Telford discussed the sites of surgical tuberculous disease and the influence of injury and pre-existing simple disease in determining the site of tuberculous infection later. The different types of cold abscesses and the results of aspiration were given. The effects of rest were discussed with special reference to the operative fixation of joints as opposed to formal excision. Finally some points were mentioned regarding the prognosis and ultimate fate of the healed cases.

LIVERPOOL MEDICAL INSTITUTION.

A MEETING of this Institution took place on Dec. 1st, Dr. J. E. GEMMELL, the President, in the chair.

Dr. W. JOHNSON read a short paper on the Diagnostic Value of the Vibration Sense. He pointed out that the work of Dr. J. L. M. Symns and Dr. E. J. Wood, in the Guy's Hospital Neurological Department, by establishing a quantitative method of estimating the sensation, had rendered the investigation of the vibration sensation at the bedside feasible. The tuning fork devised by Dr. Symns for the purpose was demonstrated. By means of it, it is possible to show the presence of a definite diminution in the vibration sense in certain nervous diseases before the cutaneous forms of sensibility show any loss. Thus the observation assumes clinical importance in the early stages of tabes dorsalis, peripheral neuritis, and lesions involving the sensory paths in the spinal cord. The point was emphasised that in cases where cutaneous sensory loss is definite, investigation of the vibration sensation is comparatively unimportant.

Mr. J. H. RAWLINSON read a paper on some Genito-Urinary Cases, drawing attention to frequent errors in diagnosis, and for their avoidance emphasised the importance of thorough investigation of the urine and catheterisation of the ureter. He contrasted the symptomatology of tuberculous pyelitis with septic pyelonephritis, the latter being more often bilateral than the former. He referred to treatment by lavage of the renal pelvis through a urethral catheter and discussed the treatment of bleeding after prostatectomy. He stated that 75 per cent. renal stones passed spontaneously and that *Bacillus coli* occurred in more than 50 per cent. of cases of pyelitis.

ULSTER MEDICAL SOCIETY.

A MEETING of this Society was held on Dec. 1st, Dr. ROBERT HALL, the President, being in the chair. The business of the meeting was

A Discussion upon the Wassermann Reaction.

Dr. J. C. RANKIN introduced the discussion, and Dr. J. A. SMYTH gave a short demonstration of the various methods of doing the test.

Dr. THOMAS HOUSTON read a paper, illustrated by lantern demonstrations, which consisted in the analysis of over 5000 Wassermann tests done by two different methods: (1) that of Colonel L. W. Harrison, and (2) that practised by Dr. Alexander Fleming of St. Mary's Hospital. The work had been done in the laboratory of the Royal Victoria Hospital by Dr. Norman Graham, Dr. George Rea, Dr. Smyth, Dr. Boyd Campbell, and himself. This analysis showed exact agreement in the results of the two tests in the vast majority of the determinations, but in 472 (or 9 per cent.) there was some difference in the readings of the two tests. These differences were further analysed and divided into diagnostic differences and differences occurring in treated cases where the tests were done for the purpose of controlling treatment. 25 per cent. of the differences occurred in cases where diagnosis was required, so that, making allowance for slight differences of degree, in about 1 per cent. of all the determinations a difficulty might arise as to which test gave the correct diagnosis. On further analysis it was shown that Fleming's method was more sensitive both in diagnosis and treatment cases, and had on several occasions given a correct finding where Harrison's method was at fault. The great drawback to Fleming's method was that in 10 per cent. of the bloods no hæmolysis took place in the control tube, and the result could not be read without repeating the test by adding fresh control serum. The reading of this test was often difficult and required considerable experience. It was therefore hardly to be recommended as a single test, but its advantages when done in conjunction with one of the other tests recommended by the Medical Research Council were obvious, and its use in this way tended to prevent mistakes. The differences shown in these analyses are in some instances, no doubt, due to errors in technique, but, as many of these differences had been confirmed by two, three, or four separate determinations, some of them were due to inherent differences in the tests.

Dr. Houston then gave an account of Prof. Dreyer's new flocculation test for the diagnosis of syphilis, and explained that it entailed only one test substance —the antigen which could be made of standard opacity by the dropping method described in Prof. Dreyer's paper. This test presented the enormous advantage of being a quantitative one. It was shown that where the readings by the other tests were different—either due to want of balance in the hæmolytic system or due to inherent differences in the tests—the Dreyer reading was low: thus the differences could be largely eliminated or assessed at their proper value. The + + Wassermann covered a very large range of reaction, from 3 or 4 units to 2000 units. An analysis was given of 300 cases in which the blood was tested by (1) Harrison's method, (2) Fleming's method, and (3) Dreyer's method. Real differences occurred in about 6 per cent. of this series of determinations, and in several instances it was difficult to say which test gave the correct finding, but on the whole the evidence was in favour of Dreyer's method. A decision as to which test gave the more correct finding required the study of a larger series of comparative tests, but it was thought likely that some form of flocculation test would eventually supplant the Wassermann technique with its inconstant hæmolytic system.

Annual Dinner.

The annual dinner of the Society was held in the Medical Institute, Belfast, on Dec. 8th. In the absence through indisposition of Dr. Robert Hall, the President, the chair was occupied by Mr. J. A. Craig, a vice-president. One hundred members and guests were present. Prof. R. J. Johnstone proposed the toast of the Prosperity of the City of Belfast, which was responded to by the Lord Mayor, Sir W. J. Coates. The Chairman gave the toast of the Houses of Parliament of Northern Ireland, which was responded to by the Marquis of Dufferin and Ava and the Hon. H. O'Neill. Prof. J. A. Lindsay gave the toast of the Legal Profession, which was responded to by the Lord Chief Justice, Mr. Justice Andrews, and the Recorder of Belfast. Dr. T. Houston, ex-President of the Society, gave the toast of the President, and coupled with his name that of the Chairman. Mr. Craig replied. The Chairman congratulated Dr. W. W. D. Thomson, the secretary of the Society, on his recovery from his recent serious illness. The dinner was one of the most successful and enjoyable in the history of the Society.

THE LATE DR. JAMES JOHNSTON.—Dr. Johnston, who qualified L.R.C.P. Edin. in 1884 and graduated in the same year M.D., C.M. at the University of Toronto, died on Nov. 25th in Jamaica, where he had been a missionary for 47 years. He was the author of a Central African study entitled "Reality versus Romance," and had written a guide for tourists in Jamaica.

THE LANCET.

LONDON: SATURDAY, DECEMBER 17, 1921.

Municipal Health Services.

As may be seen from a brief report in another column, medical practitioners in Willesden have now met the executive committees of local associations of ratepayers in a discussion of the health policy of the Urban District Council as set forth in the medical officer's forty-fifth annual health report. The memorandum,[1] drawn up by a special committee of the B.M.A., Willesden division, criticising the Council's health policy, was before this meeting on Dec. 7th and formed the basis of discussion. No formal resolution was passed, but the tenor of opinion was in harmony with Resolution 7 passed on Nov. 15th—viz., "The division calls the attention of the Willesden ratepayers to the health policy of their council, which threatens to destroy the freedom not only of the medical profession but of every individual in the community, and urges the ratepayers strenuously to oppose at the next municipal election those who are responsible for a policy which the medical profession of Willesden considers to be a serious and increasing menace to the public health." Then the ratepayers invited the doctors to coöperate in selecting municipal candidates to oppose the existing health policy. Two medical men present at the meeting were willing to become such candidates. It was pointed out by one of the medical speakers that doctors unable to serve on the Council would be ready with their advice if coöpted on the Health Committee. A local advisory medical council was suggested by another speaker as the right agency for putting health matters in the urban district upon right lines. Finally, the ratepayers expressed their appreciation of the opportunity afforded to them of conferring on local health problems with members of the medical profession, and they expressed a wish that such opportunities should be encouraged.

In Willesden it is the municipal hospital around which has centred the hottest part of the controversy. To this hospital the private practitioner has no access, and it would therefore be fair to let the Willesden health service stand or fall by the success of this nearly unique experiment, provided that those who run it have had the materials to hand for making it the success at which they were striving. A speaker at last week's meeting spoke of this hospital as a disgrace. But, as may be seen from the medical superintendent's annual statement, which appears on p. 85 of the health report, he had there to complain, in the same terms as a year ago, of a shortage of beds, of an inadequate nursing staff, and of insufficient medical help. In the year 1920, with 199 available beds, 2608 patients were dealt with by a staff of 51 nurses and two medical officers; the sickness-rate among the nurses was high, and at no time was there a clean bill of health among them; the resident medical officers were on duty seven days a week, with no break from year end to year end save for annual leave. In this hospital during the year 1920 the following fever cases were admitted: Scarlet 445, diphtheria 605, other infections 63, including typhoid 8, infantile diarrhœa 16, and erysipelas 8. Pressure upon the maternity beds was continuous; 470 cases were dealt with, as compared with 239 in the previous year; complications included placenta prævia 6, contracted pelvis 5, eclampsia 2, pelvic inflammation 5, sapræmia and septicæmia 10. Gynæcological cases numbered 81, including incomplete abortion 19, and acute mastitis 8. 524 anæsthetics were administered to operation cases, amongst them tonsillotomy 340, phimosis 44, abscess and appendicectomy each 19, for hernias of various forms 16. This amount of work is claimed to be equal to that ordinarily done at a hospital double the size, and in the view of the medical superintendent it implies an enormous strain on the limited resources. It was alleged at last week's meeting that most of the non-infectious cases might have been treated at home. There are 72 beds at the Willesden Hospital, and 330 occupied beds at the infirmary in Acton-lane. London hospitals, it was said at the meeting, were available for Willesden patients. The matter of hospital accommodation in Willesden is certainly one for the ratepayers to look into.

The health policy of the Willesden Council raises a profound question of principle which demands broad and statesmanlike handling. Preventive and curative medicine are at bottom one and indivisible. There may appear to be one glory of the sun and one glory of the moon, and the larger luminary sometimes has its radiance completely obscured by the dark side of the smaller, but the source of light is the same. It is becoming a truism to insist that the general practitioner is now and always will be the chief agent of preventive medicine. The preventist becomes all too readily a mere cataloguer of morbid conditions in relation to certain lines of civic conduct. The public vaccinator is the embodiment of business in the prevention of small-pox, but what service would he be to the community should the influence of the practitioner in the home so wane that parents lost faith in vaccination and refused to submit their children to it. Inspection of children of school age becomes a weariness to the flesh of medical men and women engaged in it, unless combined with some kind of treatment which allows them to see the fruition of their labours. In this respect, no doubt inevitably, the medical staff of the London County Council is sadly handicapped. The remedy, which is only the concentrated wisdom of the Dawson Report, is to abolish as far as possible the cleavage between preventive and curative work. It is impossible to prevent evils which you do not foresee. A practical knowledge of ill-health is the only way to acquire a real insight into the conditions of health, and the search for the earliest manifestations of disease is the chief stand-by of preventive medicine. Like goodness or purity, health is not an attainable ideal, and the immunity which appears to last is that produced by repeated small contacts with morbid influences. Innocence has little chance in an epidemic. As a nation we are proud of our administrative flexibility, and there is much to be said for each area solving its own public health problems. Willesden and Bradford have both had visions of a municipal health service without the help of the general practitioner; and indeed the branches of practice touched by municipal clinics were almost untouched by clinical medicine. Curative work on an individualistic basis had left out to a remarkable extent any effective supervision of maternity, of the nursling, and of the pre-school child. The gauntlet has now been thrown down. The Willesden division of the B.M.A. has inquired of the parent body how it is that members of the Association can be found to

---

[1] THE LANCET, Nov. 26th, p. 1124.

An excellent chapter on the medico-legal aspects of venereal disease is contributed by Dr. F. G. Crookshank. This should be carefully read by all medical officers in charge of V.D. clinics, in order that they may have knowledge of some of the pitfalls that surround them in their work.

Though the volume contains more pages it is less bulky than the first edition. It is clearly printed on good paper and copiously illustrated. Most of the pictures are excellent, but some of the coloured plates are too vivid to be true. Altogether the volume is deserving of high praise. It is the conscientious and sometimes brilliant work of one who has done more than any other in this country, perhaps in this generation, to systematise on a rational basis the treatment of the venereal diseases.

SURGERY.

A Pocket Surgery. By DUNCAN C. L. FITZWILLIAMS, C.M.G., M.D., Ch.M., F.R.C.S. Edin. and Eng. London: Edward Arnold and Co. 1921. Pp. 348. 10*s.* 6*d.*

THE value of a pocket manual on a large subject is always doubtful. It is impossible in a short compass to give a comprehensive description of the whole of surgery. There is hardly a condition in which it is possible to state dogmatically that one disease has one treatment, and in a text-book of this size it is impossible to discuss adequately alternative treatment. The student is therefore very prone to gain erroneous ideas, probably from a misinterpretation of the author's statements. The only possible way to condense such a subject as surgery is to reduce the matter as far as possible to tabular form.

The difficulties of condensation are shown by a few examples taken at random from this text-book. In the treatment of exophthalmic goitre the student is rightly told that surgical treatment is more and more replacing medical treatment; but the impression given—that the correct treatment is to remove both lateral lobes in every case—is surely not intended. In the discussion of the diagnosis of gastric surgery no mention whatever is made of the importance of the clinical history. The methods of examination are briefly given, and percussion and gastroscopy, which might be safely omitted in most cases, stand out with undue importance as diagnostic measures. We are told also that the symptoms of acute and chronic gastric ulcer are much the same, but are more prolonged in the chronic form, and that hæmorrhage in both forms may be excessive, but in the acute form is rarely fatal; as a matter of actual fact, more deaths from hæmatemesis are due to acute than to chronic ulcers. As to the treatment of the chronic variety, the advice is given to perform a gastro-enterostomy, to free adhesions, and to examine the appendix; this form of treatment sounds simple, but will not be satisfactory in all cases. In discussing the symptoms of a perforated gastric ulcer Mr. Fitzwilliams states that it is not always easy to distinguish a ruptured ulcer from a ruptured ectopic pregnancy; no attention is, however, directed to the more difficult diagnosis from a perforated appendix or an acute pancreatitis. The acute ulcer is mentioned among the causes of dilatation of the stomach, and in the paragraph devoted to treatment it is suggested that if daily lavage of the stomach does not bring about a cure a gastro-jejunostomy or gastro-duodenostomy should be performed. Mr. Fitzwilliams states that this treatment has almost entirely superseded pyloroplasty; possibly this is so, but it must be remembered that it is a form of treatment which in the acute variety of dilatation has nearly 100 per cent. mortality. The list of methods of examination for a carcinoma of the stomach is headed by distension of the viscus with gas, surely most dangerous advice.

These faults must be regarded not as peculiar to Mr. Fitzwilliams's text-book, but as likely to exist in any form of pocket text-book. Under certain circumstances the advice which can be given in a small 'pass may be correct, but it may prove very dangerous. It is therefore difficult to see quite what purpose such a book serves. No student can be advised to read it alone: it could only be recommended to one who has no time or inclination to read larger text-books, when it would assist him to take careful notes of his own cases.

Diagnostische und Therapeutische Irrtümer und deren Verhütung. Chirurgie der Wirbelsäule, des Rückenmarks, der Bauchdecken, und des Beckens. Von Geh. Med.-Rat Prof. G. LEDDERHOSE. Leipzig: Georg Thieme. 1921. With 20 diagrams. Pp. 160. M.45.

THIS little book deals with diagnostic and therapeutic mistakes likely to be made in connexion with diseases of the vertebral column, spinal cord, abdominal wall, and pelvis. It is really a small manual of diagnosis and treatment, and forms one volume in a large series of books which have been or are to be issued. The subjects dealt with in this book are a somewhat strange mixture, but the substance appears to be sound surgical doctrine.

In the differential diagnosis of tumours of the abdominal wall we could find no reference to phantom-tumour, which may certainly cause serious mistakes in diagnosis. In the section dealing with pelvic abscess no specific mention is made of diverticulitis, which is worthy of some reference. For the rest the book gives a clear account of the many pitfalls in diagnosis and treatment. The diagrams are not very good.

THE ENGLISH PRISON SYSTEM.

By Sir EVELYN RUGGLES-BRISE, K.C.B., Chairman of the Prison Commission for England and Wales; President of the International Prison Commission. London: Macmillan and Co., Ltd. 1921. Pp. 275. 7*s.* 6*d.*

IN 1910 the International Prison Congress at Washington accepted the invitation of the British Government to hold the next quinquennial congress in London; for the foreign visitors to this 1915 congress Sir Evelyn Ruggles-Brise prepared a manual of the history and leading features of the English prison system. The war prevented the realisation of all the plans, and although the greater part of this volume was prepared in 1915, it was not published till six years later, the statistics being brought up to date in most ways. The manual forms a complete and fascinating account of all the important changes that have taken place in our prison system during the last 100 years and contains interesting references to notable innovations during earlier periods in English history. It is a book which should be in the hands of every student of criminology, while several chapters, such, for example, as that on the History of Penal Servitude would interest a far wider circle.

Sir Evelyn Ruggles-Brise gives not merely a record of drastic changes with far-reaching effects, but a philosophical discussion of each problem involved. Had the manual appeared in 1915, the writer might have been hailed as a great criminologist, as well as a successful, broad-minded, and humane reformer and adminstrator. But the war drove home the lesson that conduct is essentially a reaction of mental life, and can only be understood by exploring the mind of the individual. This work contains no reference to that *magnum opus* of modern criminology, "The Individual Delinquent," by Dr. William Healy, first published in 1914; it does not go beyond the investigations of the late Dr. Charles Goring, and it author, like Goring, belongs to the rationalist school. True the manual does not profess to be a text-book of criminology, and, moreover, we may read between the lines that Sir Evelyn Ruggles-Brise is appreciative of the new ideas. He has obviously such a receptive and sympathetic mind that if the new psychologists had been able to put their case fairly before him he would soon have appraised its essential features. Had this been effected, and had he remained at the post he has now relinquished, he would have become a wise and inspiring leader. He is never deterred unanimity of this report and upon the Act of Parliament which has embodied so promptly the recommendations made. That promptitude, paradoxically, has been due to a certain lack of interest which the main body of the House of Commons showed in the Bill. The Government introduced and supported it, Parliament acquiesced, and it is now for the Dental Board and the dental profession to make the science and profession of dentistry, in Mr. Acland's words, "an effective instrument for promoting the health and efficiency of the nation."

Dental disease is as old as the history of man, but to tell the story of official dentistry in this country necessitates going back but 66 years to find the beginnings of two movements which have now reached a new and interesting stage of development. The stages have been as follows: To obtain from the medical profession recognition of the status of dentists; to secure registration and some element of self-government; to win from the public recognition of the status so granted, and of the fact that those who had attained to it were fully qualified practitioners. The Royal College of Surgeons of England was first moved in August, 1855, to appoint a board of examiners to examine candidates for "such a distinction as might well be called 'Licentiate in Dentistry,'" and in the following year a petition was presented to the same College asking it to institute an examination in the department of dental surgery, "as in midwifery." This petition was signed by 18 gentlemen, who later at a private meeting formed themselves into the Odontological Society. Others at a public meeting on the following day not desiring submission to, or dependence upon, the Royal College of Surgeons, formed the College of Dentists of England. Thus were instituted two bodies which contended together and competed as rivals until 1863, when they eliminated controversy and rivalry by a wise fusion. That there had been a deeply cut line dividing them may best be appreciated from the words of Mr. Tomes, quoted by the chairman of the Dental Board, congratulating both parties on their union and the Odontological Society on the liberal spirit with which they were amalgamating with men who had been in the habit of advertising, inducing them to give up that unprofessional practice, "to the general advantage of the profession." Meanwhile, the Medical Act of 1858 had set up the General Medical Council and had recognised and confirmed the power of the Royal College of Surgeons to confer qualification upon dentists. The charter of the Odontological Society was granted in the following year, and in November, 1871, the Council of the Royal College assigned to the certificate of the society the satisfactory and authoritative form of a diploma bearing the arms of the College and signed by its president. Gradually, however, the membership of the Odontological Society tended towards restriction to those holding diplomas, and the number of those not taking diplomas increased, necessitating a more satisfactory settlement of the anomalies of the dentist's profession which was arrived at in the Dentists Act of 1878. This followed the lines suggested by the Medical Act of 1858, and entrusted the compilation and custody of the Register to the General Medical Council, with duties attendant upon its maintenance to be carried out by a committee of five. Difficulties which then arose were freely ascribed to the fact that, strange as it may seem, the General Medical Council had not been consulted as to the framing of the Bill. Much confusion in the forming and maintaining of the Register indeed arose which appeared to the first Registrar almost insurmountable. Admissions of the undesirable from the point of view of effective dental practice were inevitable, and legal decisions construing the sections of the Act did not make its obscurities clearer for practical purposes. "As a result of these decisions," said Mr. Acland, "evils developed which gradually led to that third, final, and satisfactory solution of the troubles of the profession" which the Dental Board has now been called upon to administer.

The new Board initiates its work, as the medical profession will agree, in favourable circumstances. It is assured the goodwill and coöperation of the General Medical Council. It is composed of members representative of the interests which are to be served, skilled in administration and resolute to carry out a task the importance of which they recognise. Its chairman, a level-headed, experienced, and efficient administrator has defined the task, or the aim to which energies will be directed under his guidance, as twofold—"to guard the public from being practised upon by incompetent persons, and to see to it that there are a sufficient number of persons who will bring the most efficient dental treatment and advice within the reach of all who need it." This will not be an easy task to fulfil. It is not to be expected that ideal conditions of dentistry for crowded urban centres and for sparsely populated rural districts alike will be attainable in the near future or perhaps ever. Ideal conditions of life for all may indicate the final point towards which politicians, economists, medical men, and all others who have the welfare of their fellows at heart strive to shape their course, but, before attainment is arrived at, new ideals arise in a world in which science is in a perpetual state of forward movement. The institution of the Dental Board is a step forward in response to the dictates of science, and the effect will be of very great value in the promotion of the public health.

SIR ARTHUR PEARSON.

Sir Arthur Pearson's death in his 56th year from an unfortunate accident removes a great figure, for his name will go down as one who taught the blind not to consider blindness as an affliction but as a handicap to be wiped out by special training. His book, reissued lately under the title of The Conquest of Blindness, is striking evidence of what this indomitable spirit was able not only to visualise but to achieve. The Blinded Soldiers' and Sailors' Hostel at St. Dunstan's was one of the most successful of all the institutions for the relief of war disability. The Fresh Air Fund, founded in connexion with *Pearson's Weekly*, was the means of giving numberless poor children a recreative country holiday. His only son and heir, Mr. Neville A. Pearson, writes that his father's deepest concern was that the public should regard his work for the blind not merely as a personal effort of his own, but as a national trust placed in his hands by the people of the Empire. Continued support of St. Dunstan's and its associated hostels will be a direct monument to an incredibly busy and useful life, but his family have given a broader direction than this to any efforts that may be made in association with Pearson's honoured name. Their appeal for help for the blind is in no way confined to institutions which had direct origin in Sir Arthur Pearson's personal activities. All that can be done for the blind to lessen their disabilities in the course of life would have had Pearson's support, and any help rendered to the blind, and proffered in his memory, will be an act of appropriate recognition of a splendid career.

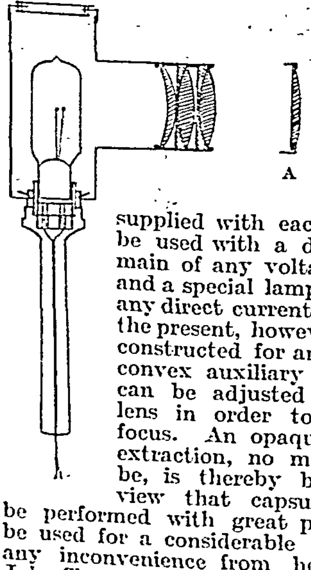
authors set forth their method in detail, and they find that it is possible to measure the oxygen pressure in blood drawn directly from a vessel in man to within about 2 mm. on the average, and they confirm experimentally the dissociation curves for venous blood calculated by Douglas, Haldane, and others, as well as the observations of Meakins and Davies on the great range of unsaturation of blood from the basilar vein when the arm is exposed to widely differing temperatures. The experiments indicate a fifty-fold alteration in the volume of blood traversing the skin of the arm per minute.—The Effects of Adrenalin upon Respiration, by Ff. Roberts. It has long been known that adrenalin, when injected into an animal, induces a profound change in respiration. The author, after noting the results of previous observers—from 1895 onwards—describes his own observations on anæsthetised rabbits and cats. The Parke-Davis 0·1 per cent. solution was used—the dose commonly employed was 1 c.cm. of 0·01 per cent. adrenalin, sometimes 1 c.cm. of 0·005 per cent. or of 0·1 per cent. The tube connecting the artery and manometer for the blood pressure experiments was filled with pure Ringer's solution. Adrenalin in large doses, besides causing diminution and temporary arrest of respiration, causes alteration in rate, and may cause Cheyne-Stokes respiration, and the diminution and arrest occur when there is no change in blood pressure and are mainly central in origin. The respiratory effects are caused by sudden anæmia of the respiratory centre due to vaso-constriction. The author found no evidence that adrenalin causes nervous impulses from the periphery.—Other communications include The Action of Carbon Dioxide on Salt and Water Distribution in Blood, by Genko Mukai; The Measurement of the Oxygen Content of the Mixed Venous Blood, and of the Volume of Blood Circulating per Minute, by J. Barcroft, F. J. W. Roughton, and R. Shoji; Variations in Alveolar Carbon Dioxide Pressure in Relation to Meals, by E. C. Dodds and T. Izod Bennett; Studies on the Physiology of Capillaries, by August Krogh; On the Path of Conduction between Auricle and Ventricle in the Amphibian and Reptilian Heart, by D. T. Barry; The Electrical Response of Denervated Muscle, by E. D. Adrian; The Nature of the Isometric Twitch, by W. Hartree and A. V. Hill; The Relation of Pulse Pressure to the Output of the Heart (as investigated on the heart-lung preparation), by Ruth Skelton; and Exosmosis from Animal Cells, by J. Gray.

IN the AMERICAN JOURNAL OF OPHTHALMOLOGY for October G. F. Garraghan writes of a case of papilloma of the cornea in a man of 70. A tumour grew from the sclero-corneal limbus and attained such size as to overlap more than half the cornea. It was excised and, histologically, showed the structure of a papilloma. It subsequently recurred more than once. These tumours are rare; they occasionally become malignant.—F. Yano describes a typical circinate retinitis in a boy of 13. It is only in old people that this disease is usually observed. The vision was down to 0 in one eye and 0·1 in the other. The ring of white exudation enclosed both macula and disc. At the macula itself in each eye was a white plaque of exudation.—A. C. Macleish describes keratitis caused by excessive sugar ingestion. Over-indulgence in sweets by children is said to be responsible for many cases of conjunctivitis, blepharitis, phlyctenules, and facial eruptions. In the case described there was a distinct interstitial keratitis in a child of 3. There was a negative Wassermann reaction. It was found that the child ate a large quantity of sugar daily; when this was stopped the trouble disappeared, recurring when the interdict against sweets was removed.—Oscar Dodd reports a case of repeated operations for glaucoma. After a recurrence following upon a Lagrange operation, a sclero-corneal trephining operation was performed. This was followed by hypotony, iritis, and cataract. After extraction of the cataract the tension again went up and a second trephining operation was formed. The trephine hole got blocked up with thickened membrane, which was subsequently removed. There was a family history of glaucoma in this case, but the second eye did well after a single operation.—Ellice M. Alger describes three cases of word-blindness. One of these cases was associated with an attack of right-sided hemiplegia in a man of 59 with a positive Wassermann reaction, leaving a right homonymous hemianopsia, with a total disability to read letters or words though visual acuity was good, numbers being read normally. This disability gradually disappeared, although the hemianopsia remained. The other two cases were congenital. Visual memories seem to be stored in the region of the left angular gyrus in right-handed people, and the theory of acquired word-blindness is that the connexion between the visual centre in the occipital lobe and the angular gyrus is somehow interrupted. In the case of congenital word-blindness the defect is probably in the development of the cortical centre itself and may be of varying severity. The importance of recognising the condition lies in being able to disabuse the minds of the parents or teachers who often take the inability to read as stupidity, while all the time the mental condition of the child may be normal in all other respects. Improvement may be effected by special methods of teaching.—Eugene M. Blake in a paper entitled Ocular Changes in Infantile Scurvy states that exophthalmos due to hæmorrhage into the orbit is a not infrequent symptom of the infantile scurvy, and was first described by Sir Thomas Barlow. It may even be the first symptom, and the child may first be brought to see the oculist. When the correct diagnosis was established in this case the diet was changed from artificial foods to fresh cow's milk and orange-juice, and the child quickly recovered under antiscorbutic measures.—The notes in this number include illustrations of a foreign body spud illuminator by W. H. Lowell and a new test-card by J. M. Thorington.

New Inventions.

AN OPERATING HAND-LAMP FOR OPHTHALMIC WORK.

FOR several months I have been using a hand-lamp in which the source of illumination is the "pointolite" electric lamp of the Ediswan Co., and as I have been so satisfied with it in all operations on the eye, I venture to bring it to the notice of ophthalmic surgeons. The lamp is of 30 candle-power and is enclosed in a metal case with an aperture on one side in which a system of achromatic lenses is so fixed that the emergent rays are parallel. By this means the field of operation is evenly illuminated by a disc of light free from all shadows. A resistance is supplied with each lamp, whereby it can be used with a direct current from the main of any voltage between 100 and 250, and a special lamp can be got to work on any direct current down to 32 volts. Up to the present, however, a lamp has not been constructed for an alternating current. A convex auxiliary lens (A) of 3 dioptres can be adjusted in front of the fixed lens in order to bring the light to a focus. An opaque capsule after cataract extraction, no matter how thin it may be, is thereby brought so clearly into view that capsulotomy operations can be performed with great precision. The lamp can be used for a considerable length of time without any inconvenience from heating. It is made by John Trotter, Ltd., Gordon-street, Glasgow.



Glasgow. A. MAITLAND RAMSAY, M.D. Glasg.

its consideration. The particular point which he has investigated is whether the relation of the volume of the trunk to the length of the limbs can be correlated with the intelligence, as ascertained by one of the several systems now in profuse use in America. Those with a relatively small trunk and long limbs are, after Viola's classification, microsplanchnics, while those with a trunk excessively developed in comparison with the arms and legs are macrosplanchnics. Viola held that the microsplanchnic, departing as he does as far as possible from the infantile habit of body, may be regarded as hyperevolute, and for this and other reasons of similar validity the presumption arises that intelligent individuals are more likely to be found in this group than among the macrosplanchnics, which tend to maintain the proportions of infancy. The microsplanchnic is to be looked upon also as having a relatively more active thyroid, owing to the connexion between the thyroid and growth in length. Generally speaking, therefore, Dr. Naccarati concludes that macrosplanchnics excel in instinctive reactions such as eating and sleeping, which satisfy the somatic self, and in capacity for prolonged steady physical and mental work, while microsplanchnics are more intelligent in the ordinary sense, have greater intuition and mental agility, are more easily exhausted, and excel in connexion with the psychic self. Whether the rather meagre data presented by the author adequately confirm these interesting propositions is questionable. On 75 subjects the coefficient of correlation between his "morphologic index" (a measure of microsplanchnicity) and intelligence is only +0·36; on the ground that the correlation of height-weight ratio with morphologic index is +0·7, he uses the two measures alternatively; in 221 subjects the correlation of intelligence with height-weight ratio is +0·23—figures which would hardly justify examinations by anthropometry. We hope, therefore, that it will be possible for some determined macrosplanchnic to verify, as so often happens, the microsplanchnic's intuition. If his intelligence has led him rightly, it suggests that the common criterion of beauty has a more spiritual basis than might be suspected.

THE MENTAL EXPERT IN THE MAGISTRATE'S COURT.

THE need for the modification of certain social demands to meet certain individual cases and the provision of more sympathetic treatment for those who find it difficult to conform to laws made for the common good has been prophesied by Samuel Butler, Brieux, and John Galsworthy. For even where the writings of these idealists are designed to show abuses and anomalies in our system their widespread popularity is at least an indication of the dawn of a wider view. Dr. J. T. Dunston returns from a recent visit to America with the impression that there it is the individual who really matters, not the crime, and gave to the Medico-Psychological Association, at a meeting which we report on p. 1275, a brief account of the part now played by the psychologist in transatlantic law-courts. To the same meeting Dr. M. Hamblin Smith, medical officer at Birmingham prison, offered some pregnant suggestions arising out of his experience of the working of a scheme initiated in Birmingham in 1919. This scheme for dealing with accused persons brought before the magistrates in order to secure, if possible, treatment in accordance with their mental condition was outlined in THE LANCET [1] a year ago. A report on the continuation of this work presented to the justices of Birmingham by their General Purposes Committee, defines the relative functions of Dr. Hamblin Smith and Dr. W. A. Potts, whose lecture on the Relation of Crime and Delinquency to Heredity, Environment, and Disease appeared in our columns recently.[2] According to the report, the detention of the offender on remand for a period, which has been usually of a week's duration, has enabled the medical officer to give helpful information to the court. In cases where it has not been necessary or desirable to remand the offender to prison, the case has been adjourned for medical examination, a procedure with special convenience in the case of children. Dr. Potts expresses regret that more cases should not be referred to him, and suggests that reference should not be confined to occasions where it appears to be necessary. Dr. Hamblin Smith criticises the objection raised by some persons to the remanding of cases which might be admitted to bail. He explains that the examination into the mental condition of offenders is necessary, and can best be made in an institution where they can be under close observation. Those examined by him are treated in the remand department of the prison under what he describes as hospital conditions, the idea of prison being kept out of sight. It is to be hoped that the Birmingham experiment will be tried before long, on a larger scale and in other cities, under the direct authority of the Government.

RELATION OF THE SPECIES OF RAT-FLEAS TO SPREAD OF PLAGUE.

THOSE who are engaged in its study find the epidemiology of plague a most absorbing problem in view of the many variable factors which come into play. An investigation into the conditions commonly needed for an epidemic of human plague was carried out in a very thorough manner by the Plague Commission in the early years of this century. Since then research work, although greatly retarded by the war, has been going on steadily throughout the world wherever plague has manifested itself. We referred recently to the work of Kunhardt and Chitre, and have published an account of the outbreaks in some rural districts of South Africa. Attention is now drawn to the work of Major F. W. Cragg, I.M.S., who has further advanced our knowledge by a careful scrutiny of the species of fleas that live on the rats in various parts of India. In the October number of the *Indian Journal of Medical Research* he has contributed some further preliminary observations in which he discusses the geographical distribution of the Indian rat-fleas as a factor in the epidemiology of plague. The Plague Commission workers recognised that there were several varieties of fleas on rodents in the East and they were aware that *Xenopsylla cheopis* was the most efficient carrier of the virus. Major Cragg goes into the matter much more thoroughly and shows that there are two other species met with—namely, *X. astia* and *X. brasiliensis*, and that the capacity of each of these three species to spread plague is not the same. The two most widely distributed species in India, cheopis and astia, vary greatly in this respect, the former being an efficient carrier of the infection, while the latter has little capacity to act as a vector of plague. Major Cragg, therefore, has made attempts—as yet, it is true, on no very large scale—to ascertain the species of rat-flea that predominates in heavily-infected areas, as also in districts which have escaped the infection or suffered only slightly from it during the present pandemic.

In response to his requests, Major Cragg has received for examination 107 separate collections of local rat-fleas from various provinces, including the Punjab, the Presidencies of Bombay and Madras, Burma, and Central India. These collections comprised 17,358 rat-fleas, of which 9330, or 53·9 per cent., were *X. cheopis*; 6241, or 36 per cent., were *X. astia*; and 1334, or 7·7 per cent., were *X. brasiliensis*. In addition there were 307 specimens of *Ceratophyllus* and 67 *Leptopsylla musculi*. The Punjab contributed 5088 of the rat-fleas, Bombay Presidency 5183, Madras Presidency 4491, Burma 1697, and Central India 280. The majority of the rat-fleas from the Punjab and Bombay were *X. cheopis*; from Madras and Burma *X. astia*, and from Central India *X. brasiliensis*. Roughly, 90 per cent. of the fleas sent for examination belonged to the two species cheopis and astia. Major Cragg frankly admits that his observations so far accept positions in such a health service. The current issue of *Public Health* points out to the Association that if it embarks on a campaign against this service it shows its intention to ally itself with any and every reactionary force in order to oppose the natural development of public medical services. We believe that the solution in Willesden, as in Bradford, must needs come—neither confounding the persons nor dividing the substance—along the lines of a local medical advisory council.

◆

Adenoids.

Chronic hypertrophy of the nasopharyngeal tonsil, the condition commonly known as "adenoids," is to be found all over the surface of the globe, but it is more frequent in damp temperate climates, and is perhaps commoner in England than in any other part of the world. Here it is amongst the commonest diseases of childhood; it produces disabilities of far-reaching importance and, although the hypertrophy usually disappears about puberty, much of the damage it has done remains throughout life, and constitutes a mass of disability of serious import to the State. The mechanical obstruction to nasal breathing produces deformities of the face and chest which permanently impair the normal respiration; infection spreads from the pharynx to neighbouring parts, causes cervical adenitis, and is responsible for a large amount of the catarrhal and suppurative disease of the ears which disables a multitude of our population; infection also reaches the gastro-intestinal tract, and the relationship of adenoids to such diseases as rickets and appendicitis has been the subject of inquiry in various quarters. Adenoid children are often dull and apathetic, though the reason of this peculiar "aprosexia" has not been satisfactorily explained. In addition to all this, various neuroses are related to the presence of adenoids; they form a long list, and include laryngeal spasm, asthma, stammering, habit spasms, enuresis, and even epilepsy.

The enumeration of the ill-effects of adenoids makes such a formidable array that we must guard against the error of supposing that all the affections in the long list are always due to this cause; particularly is this the case among the so-called "reflex" effects, for no one supposes that epilepsy or enuresis, for instance, are only caused by adenoids, or that there is no other factor in their production; not all children with even large adenoids are dull and backward, nor do deformities of the jaws and palate necessarily result. On the other hand, it should be remembered that adenoids in a roomy nasopharynx may cause no nasal obstruction, and yet may produce inflammation of the ears. The effects of adenoids, as well as the final results of treatment, come more constantly under the observation of the general practitioner than of the specialist. A paper by Dr. H. Merrall appeared in The Lancet of Nov. 12th which dealt with some of the results he had observed. Naturally all his conclusions will not find universal acceptance, and some have indeed stimulated discussion. Among these we note his statements that enlargement of the palatine tonsils is always secondary to enlargement of the pharyngeal tonsil, and that flat-foot is an almost invariable accompaniment of adenoids; while the success of the adenoid operation in curing such affections as epilepsy, chorea, and nocturnal enuresis, and the inter-relationship of adenoids and rickets, remain as fields of observation and research. We have been informed by Dr. J. W. Kynaston that a Council has now been formed representing the belief among certain qualified medical practitioners that "operations for nasal obstruction are being altogether overdone." This Council for the Promotion of Oro-Nasal Hygiene has a secretary who may be communicated with at 26, Welbeck-street, London, W. Now the presence of adenoids is one of the principal causes of nasal obstruction. With such a category of possible ills due to the presence of adenoids as that just set out, those who criticise the clinical actions of their colleagues in making a practice of operating will require a good deal of positive evidence before proving good their case. The positive evidence, to be really useful, would mean the records of a very large number of cases where the presence of adenoids has been undoubted at a previous period, and where non-removal has led to no ill consequences.

We publish in another column a paper by Mr. David Ranken, nose, throat, and ear specialist to the R.A.F. Medical Service, in which are set out problems presented by the international medical requirements for air navigation with special reference to nose, throat, and ear. *It is the common opinion* of those who sit upon medical boards for the examination of candidates for aviation that a pilot should be organically sound, especially in regard to the nose, throat, and ear, but the notes of actual examination of candidates given by Mr. Ranken show that the commonly accepted regulation can be set aside in particular cases, and that there is an admirable absence of pedantry in the verdicts upon those who present the results of old nose or throat and ear trouble. Of adenoids it is said that the candidate in whom they have been discovered is not rejected for that alone, nor is operation insisted upon where mouth-breathing constitutes apparently no disability. The assessment of the symptoms determines the results of the examination. Medical boards which examine candidates for aviation have, therefore, before them the material upon which some collective and considered judgment could be given as to the place which operation plays in the treatment of adenoids. From these boards particular information might be obtained in time upon the following points: the number of candidates who, having adenoids, can still rank as practically sound; the number whose remaining disabilities are due to neglected adenoids; the number with adenoids who are rejected for deafness; and the number able to pass the hearing tests, who have been operated upon already. If figures like these could be collected in some mass, the results would be very useful to the medical profession.

◆

The Dental Board.

On Dec. 7th was opened the first session of the Dental Board of the United Kingdom, a title which in view of current political developments may have to be revised. The Board, which consists of appointed members has as its first duty to construct and assemble the machinery for carrying out the Dentists Act of 1921. The members will hold office for such term not exceeding three years from the commencement of the Act (July 28th, 1921) as the Privy Council may determine, and after the expiration of whatever period may thus be fixed a Board consisting of seven appointed and six elected members will carry on the work so initiated. In opening the session the chairman of the Board, The Right Hon. F. Dyke Acland, M.P., referred to the committee over which he had presided in 1918, a body appointed to report upon the extent and gravity of the evils attending dental practice. He is to be congratulated upon the conditions—appendicitis and peritonitis. But, perhaps, their more especial interest lies in their relationship to public health, as providing evidence of the contamination of water-supplies by fæcal matter. Any study of intestinal bacteria brings to light the varying nature of the flora of the normal intestine, which shows noteworthy changes from day to day and from season to season. Moreover, with the changes in the intestinal juices and variations in the rate of passage of the intestinal contents which are induced by disease, we must expect alterations in the fæcal flora, and probably this is why in dysentery we find organisms closely related to, but not identical with, the causal organism coming to the fore with such frequency. Correlated with other variations in the condition of life we should expect changes in the intestinal organisms, and it must be conceded that standards which apply to the average person in this country may not be accurate under changed conditions, and that it may be necessary to establish the normal by fresh research where new communities come under observation. An investigation of this sort has been undertaken by Dr. H. L. Duke, whose results we published last week, on the fæcal flora of whites and natives in Uganda. The data given are not sufficiently numerous to allow of permanent deductions, but they are sufficient to show that there is apparently a high incidence of the non-pathogenic non-lactose fermenters, whose exact identification is a matter of importance in view of their tendency to cause confusion with the virulent organisms so frequent in this class.

It is an interesting problem to what extent the presence of one property in an organism demands the presence of another, and vice versa. We see how often inability to ferment lactose is associated with the power of invading the human body. It is also a general law, observable not only in the class of organisms which we are now discussing, but also amongst the streptococci, that in a wide way there is an association between pathogenicity and inability to attack and ferment many of the carbohydrates. The idea is a very attractive one, that this represents a fundamental divergence of a common stock into two branches—the one mainly a saprophytic group and existing largely on carbohydrate foodstuffs; the other preferably parasitic, and sacrificing ability to utilise carbohydrates to gain the power of attacking protein substances, which is essential to a life of parasitism.

ESSENTIALS OF MENTAL HYGIENE.

THE Board of (Lunacy) Control has invited the chairmen of visiting committees and the medical superintendents of public mental hospitals to meet the members of the Board in conference at the Ministry of Health on Jan. 10th next, with the object of considering how to improve lunacy administration and the treatment of persons suffering from mental disease. The letter summoning this conference points out that although it is important to reduce expenditure it is essential, and in the end economical, to do everything practicable to prevent mental disease and to cure it when it occurs. The Board desires to exchange views with those engaged in the actual administration of mental disease. If this conference proves worthy of the circumstances which have led up to it, we are on the verge of better things in the field of psychiatry, and it is not without significance that this moment has been chosen for the foundation in France of a League of Mental Hygiene, whose first *Bulletin*[1] has just appeared. This League has set itself to attack the problem from all sides and its first endeavour is to provide treatment for uncertifiable and incipient cases of insanity. The authorities of l'Asile Clinique in Paris have already been persuaded to make provision for voluntary boarders, and several out-patient clinics have been established there and in other parts of France. Meanwhile, 10 commissions have been appointed to investigate and report on other aspects of mental hygiene. Among these, the problem of ætiology figures largely—the relation of toxic states to mental disease, the effects of alcoholism, drugs, and other external toxins, psychopathic predisposition, the effects of different occupations, and the choice of occupation in accordance with mentality. The problem of protecting society against the example and other dangers inherent in the mental perverts who make up the class of habitual criminals is to be considered, and that of the education of defective children. The adequate teaching of psychiatry, and the propagation of research are also aims which the League hopes to further. Finally, it has set out to educate the public. So much insanity is avoidable that a more general understanding of the causes going to produce it may have far-reaching effects. The League aims at affiliation with similar societies in other countries where the needs are very similar. The sufferer from early mental disease is the most neglected type of patient we know. At a general hospital the verdict "functional" is often equivalent to a plain statement that the patient must help himself. Existing staffs have neither the time nor the special ability required for the treatment of neuroses, drug habits, and functional mental disorders of types which are to be met every day. The Medico-Psychological Association of Great Britain and Ireland has done much to stir the public conscience in these matters; the French League of Mental Hygiene is a movement in the same direction whose progress will be followed with keen interest in this country.

THE VALUE OF PERIODIC HEALTH EXAMINATIONS.

AT present the medical practitioner refrains from paying a professional call on a family of patients until a sick member or his relatives regard an attack of illness as serious enough to demand medical care; if these necessary visits were supplemented by periodical medical examinations of each member of the families in the doctor's practice, much ill-health could doubtless be avoided. On this assumption the Life Extension Institute of New York has been organised. For a collective fee or an annual subscription examination of the insured persons is obtained at periodical intervals, the examination being conducted by specialists and a collective report on the patient being made. In a recent annotation we noted that the Metropolitan Life Insurance Company of New York had arranged for skilled nursing of many of their sick clients, and for visits by public health nurses at the expense of the company. The same enterprising company have been carrying through another interesting experiment, the results of which have recently been described by Dr. A. S. Knight, its medical director. This experiment, which has been on trial from the year 1914 onwards, consists in making available for the policy-holders of the company a periodical medical examination, which has been undertaken for the company by the Life Extension Institute. Leaflets were issued with every annual premium notice urging the examinations, telling the policy-holders that the results would be strictly confidential and, particularly, would *not* be revealed to the company, and that the insurance would not be affected in any manner. Under this scheme some 95,000 examinations have been made, or 7·8 per cent. of the estimated number of eligible requests for examination. Of this number over 5987 males were available for statistical study, having been examined during 1914 and 1915, a long enough interval to allow of comparisons. The results of this comparison are to some extent rendered liable to the errors of small numbers by the necessary division into smaller groups. The aggregate result appears to have been that in the year 1915–16 the cases examined by the Institute showed a mortality of 39 per cent. of the American Experience Table,

Annotations.

"Ne quid nimis."

MEDICAL HISTORY OF THE WAR.

THE first volume of the Official Medical History of the War, which has now been completed by Major-General Sir W. G. Macpherson, K.C.M.G., C.B., LL.D., will shortly be available to the public. The series, of which Sir William Macpherson is editor-in-chief, is so planned as eventually to comprise 12 volumes: General History of the Medical Services (4 volumes); Diseases of the War and the Medical Aspect of Aviation and Gas Warfare (2 volumes); Surgery of the War (2 volumes); Hygiene of the War (2 volumes); Pathology and Medical Research during the War (1 volume); Medical Statistics and Epidemiology of the War (1 volume). The main object in preparing a consecutive history is to present in an accessible form the material buried in masses of war diaries, administrative files, official reports and other documents, before they have been stored away and their existence forgotten except by a few. The first volume is a record in narrative form of the medical services in the United Kingdom and in garrisons overseas, with an account of the medical services in the operations against the German colonies in West and South-West Africa and in Tsingtau. Including labour units provision had to be made at one time or another for the medical services of forces with a total strength of nearly 3,500,000 operating in every variety of country and climate. A total maximum of 637,746 hospital beds were maintained in the United Kingdom and in theatres of war, and some 770 medical units of all kinds were mobilised and despatched to expeditionary forces. In addition 75 hospital ships or ambulance transports were equipped and administered by medical services in the United Kingdom, and 2,655,025 sick and wounded were brought to its shores for further treatment and disposal between August, 1914, and August, 1920. The personnel for medical services numbered at the time of the Armistice 144.514 officers and other ranks, most of whom joined the Royal Army Medical Corps and were trained in the United Kingdom. The volume will shortly be available through any bookseller at the price of £1 1s.

ALASTRIM.

THE question of the identity of alastrim with small-pox must still be regarded as unsettled. A paper by Drs. W. G. MacCallum and L. M. Moody on an Outbreak of Alastrim in Jamaica during the Autumn of 1920, published in the *American Journal of Hygiene* for July, contains much interesting matter, but offers no definite conclusion on this main problem. The authors state that "there are very few recorded instances of the transportation of this disease to other climates," so that special interest attaches to the fact that, about the time that this outbreak was in progress in Jamaica we referred[1] to an outbreak of alastrim occurring in East Anglia. The Jamaica outbreak was on a much more extensive scale; in September, 1920, the number of cases in Kingston at any one time was variously estimated at 400 to 700, of which about 325 were isolated in a building outside the city. The disease appeared in Kingston in May, 1920, and is believed to have been imported from Cuba or possibly from South America, although the exact mode of introduction was not determined. In all 2333 cases were reported, the majority of them among the native population. The clinical history of the disease given by Drs. MacCallum and Moody corresponds fairly closely with that which came under observation in this country, the main points of divergence from typical small-pox consisting in the fact that although the initial symptoms might be severe, the disease was on the whole of extraordinarily mild character, the mortality-rate hardly exceeding 0·5 per cent. of those attacked. Backache was rarely severe, and the eruption, which in the vesicular stage was not umbilicated, came out in successive crops. On recovery no deep pitting or scarring of the skin remained. The marked odour so characteristic of small-pox was entirely absent.

The relation of vaccination to the disease is of special importance. Dr. Moody, who made a careful study of the question in 206 adults and 80 children, found evidence in the former class that the proportion of severe cases was higher among the non-vaccinated, but adds that since none of these people had been vaccinated more recently than 20 years ago, not much stress can be laid upon his figures. Among children he found a general tendency to a milder type of the disease especially marked in the vaccinated group, among whom not a single severe case occurred. He further states that he vaccinated 20 persons who had been in contact with the disease without one instance of subsequent infection; while in several households that came under observation unvaccinated members of the family contracted the disease while the vaccinated escaped. On the other hand, of 60 cases vaccinated at varying periods during convalescence, 45 "took" to some extent, although in no instance did they give a typical reaction as compared with normal controls. It was not found possible to transmit the disease experimentally to rabbits or calves. Perhaps the most interesting section of the report is concerned with the histological appearances of the skin in alastrim, as studied in sections of pocks excised in various stages of development. From the descriptions given, as well as from the excellent photographs, clinical and microscopical, with which this study is illustrated, it would seem that the stages met with in the evolution of the eruption follow more closely those observed in vaccinia than in small-pox. Comparison of the results of Dr. Moody's investigation with the illustrated monograph on the Histology of Vaccinia by Dr. S. M. Copeman and Dr. Mann, published as an appendix to the Report of the Medical Officer to the Local Government Board for 1902, confirms this impression. Although allied to both small-pox and vaccinia alastrim obviously cannot be regarded merely as a mild form of varioloid in which the eruption is likely to be sparse; a marked characteristic of alastrim is the occurrence of a more or less confluent eruption in a patient who in most instances is never seriously ill.

THE MORPHOLOGICAL ASPECT OF INTELLIGENCE.

IN more than one place in Thomas Hardy will be found a curious reflection on the alteration which has taken place among Western civilisations in the criterion of male facial beauty. We no longer, he has pointed out, adopt the standard of pure perfection of line and surface which satisfied the Greeks, but demand before we call a face beautiful that it should bear the marks of intellectual and emotional virility and action, the scars, perhaps, of mental and spiritual conflict. If it be possible to arrive at some association between bodily form and intellectual character, we may presume that our criterion of bodily beauty might change in the same way and no longer rest as at present, partly on a purely artistic basis, and partly on the idea that a body which can achieve bodily, and mostly athletic, success must be held to be beautiful. No settled opinion has been reached even in this relatively simple field, for Carpentier, who boxes supremely, is beautiful, while Shrubb and Dorando, who run like deer, are not. It is therefore not to be wondered at that the difficult problem of discovering whether there is any connexion between bodily form and intelligence is still far from solution, and an interesting discussion[1] by Dr. Santi Naccarati is a welcome contribution to

[1] THE LANCET, 1920, ii., 1153.

[1] Archives of Psychology, August, 1921.

Italy: B. Gosic, Chef de Laboratoire de Bactériologie, Direction Générale de Santé, Rome.

Japan: Dr. M. Miyajima, Kitasato Institute, Japan.

Poland: Dr. L. Hirszfeld, Director of the State Serum Control Institute, Warsaw.

Switzerland: Dr. R. Doerr, Professor of Hygiene and Bacteriology at the University of Basle.

Dr. L. Rajchman, Medical Director, League of Nations; and Dr. F. Norman White, C.I.E., Chief Epidemic Commissioner, League of Nations, acted as secretaries, while the following British technical advisers attended the conference:—

Medical Research Council: Sir Walter Fletcher, K.B.E., M.D., F.R.S., Secretary of the Medical Research Council; Prof. G. Dreyer, M.D., F.R.S.; Dr. M. H. Gordon, C.M.G.; Prof. J. C. G. Ledingham, C.M.G., F.R.S.; Dr. P. Fildes; Capt. S. R. Douglas, I.M.S.

Ministry of Health: Col. L. W. Harrison, Specialist Medical Officer for Venereal Diseases; Dr. A. Eastwood (Pathological Laboratory.)

War Office: Sir William Leishman, K.C.M.G., C.B., F.R.S.

The conference came to a conclusion on Wednesday afternoon with the reception in plenary congress of the reports of the six subcommittees appointed to consider the international standardisation of sera in connexion with diphtheria, dysentery, various types of meningococcus and pneumococcus, syphilis, and tetanus.

AMŒBIASIS.

FROM the general survey by acknowledged experts of the significance and treatment of amœbic dysentery, which took place at the Section of Tropical Diseases and Parasitology of the Royal Society of Medicine on Dec. 5th, several interesting conclusions emerged. A point emphasised by Prof. L. S. Dudgeon and Sir Leonard Rogers was the present rarity of liver abscess, a complication which in pre-emetine days was computed to affect one in seven cases of amœbic dysentery. Another point generally agreed upon was that, although emetine is almost a specific in the acute stage of amœbic dysentery, it had not proved so efficacious in the more chronic and intractable clinical forms of the disease met with during the war and since the cessation of hostilities in war pensioners. The toxic effects of large doses of emetine have apparently been exaggerated; they occur only in specially susceptible individuals, and take the form of pareses of certain groups of muscles, peripheral neuritis, and a branny desquamation of the skin. Some difference of opinion still exists as to the value of the exhibition of the double iodide of emetine and bismuth; Dr. P. Manson-Bahr contended that where attention is paid to subsidiary methods, such as intravenous injection of neosalvarsan and lavage of the large bowel by eusol and to details of the dietary, these drugs produce good results in 70 per cent. of cases. Red meat and starchy foods should be avoided during convalescence, and a carefully regulated regimen should be drawn up for each patient. The adoption of more uniform standards of treatment and of recording results are obviously desirable if reports from different workers are to be compared. Amœbiasis can remain latent for a much longer period than is generally supposed, and relapses have been recorded after a quiescent period of six years. It would seem that though the mortality of the disease has diminished enormously since the introduction of emetine, an absolute cure can only be hoped for when the diagnosis has been made early and the treatment has been prompt and thorough.

GAS INFLATION OF THE PERITONEUM IN RADIOGRAPHY.

OXYGEN-DISTENSION of the peritoneal cavity for radiographic purposes was introduced in 1913 by E. Weber[1] and has been taken up since in Italy and America. J. E. H. Roberts[2] in this country recently gave some of his results with a plate showing spleen, kidney, uterus, and mesenteric cysts clearly defined by this method. At a meeting of the Section of Electro-Therapeutics of the Royal Society of Medicine held on Dec. 9th, Dr. Carelli of Buenos Aires described the method as elaborated in his hands. He demonstrated a number of skiagrams showing the outlines and position of the liver, spleen, pancreas, uterus, ovaries, and Fallopian tubes. In some of the skiagrams appeared, in addition, the distended gall-bladder and the kidneys. In cases of cirrhosis of the liver the irregular outline of the organ was clearly visible. In cases of hydatid disease cysts in the liver and spleen were to be seen. In cases of cholelithiasis calculi were revealed. The demonstration, in fact, made it clear that it is possible by this relatively new method of radiographic examination to obtain information on the position, size, shape, and relations of the abdominal viscera over and above that given by the methods generally used. For injection Dr. Carelli prefers carbon dioxide to oxygen, and he advises the removal of the gas after the radiographic examination. As the outlines of the kidney are not always shown by the X rays after distension of the peritoneal cavity with gas, Dr. Carelli conceived the idea of injecting gas into the peri-renal fat and producing an artificial emphysema around the kidney. He has performed this operation several times with success, and has been able to demonstrate the kidney with the same clearness as the other abdominal viscera. He has succeeded thus in showing the suprarenal gland, the first time, we believe, that this organ has been rendered visible during X ray examination. Skiagrams were shown at the meeting in which the outlines of kidney and suprarenal, both normal and abnormal, were clearly indicated. The attendance at the meeting was evidence of the keen interest which is being evinced in this addition to the radiographer's diagnostic equipment.

NEW LIGHT ON ANGINA PECTORIS.

THE careful and painstaking work of Sir Charlton Briscoe on the origin of the anginal syndrome, as set out at the Harveian Society in an address which we print this week, throws new light on an attractive subject in which speculation has been rife. In the discussion Sir William Willcox agreed that pain resulting from over-fatigue of certain respiratory muscles might be referred to areas corresponding to those which occur in angina pectoris, but he could not admit muscular fatigue to be a complete explanation of the painful symptoms of angina. Sir James Mackenzie has always stoutly maintained that the gripping pain of angina is due to spasm of the intercostal muscles and therewith an effect and not a cause of angina. If the pain of angina pectoris were due to fatigue of certain respiratory muscles, why, Sir William Willcox asked, did not anginal attacks accompany illnesses such as bronchitis, pneumonia, laryngeal obstruction, in which these muscles were submitted to very great over-exertion? Typical attacks of angina appeared to follow slight exertion where the question of muscular fatigue could hardly arise. However produced, the pain of angina is a condition for which any suggestion of relief would be welcome. In the *Bulletin* of the French Academy of Medicine of Oct. 25th, Prof. T. Jonnesco, of Bucharest, recorded a severe case of angina in a man aged 51, who presented the typical symptoms, and for whom life had become almost insupportable owing to excruciating attacks of pain induced by walking or the least emotion, and intensified by slight changes in the weather. The patient showed dilatation of the aorta, together with chronic bronchitis and emphysema. The Wassermann reaction was positive. Anti-syphilitic and other forms of medical treatment having failed to give relief, he decided to submit to surgical measures. Under dorso-cervical spinal anæsthesia Prof. Jonnesco divided the left cervico-thoracic sympathetic nerve on June 13th, 1921. The relief was immediate, and during the months of July to October are neither sufficiently numerous nor evenly enough distributed to give definite results. The collections of rat-fleas sent to him varied greatly in size, and at best represented only a portion of the country; they were not made in a manner calculated to eliminate the error due to the uneven distribution of the species in the particular locality they represented. Nevertheless, the results are striking. Though the nature of the records is not well adapted for the application of the statistical method by which such a problem should be approached, yet the observations, in Major Cragg's opinion, point very strongly to a close relation between the predominance of X. *cheopis* and a high plague mortality, and that that flea is "the true plague flea" of India; on the other hand, X. *astia* is the predominant rat-flea in those areas which are known to have remained free from plague epidemics, or which have only suffered slightly from the disease. The liability to severe epidemics of plague in those regions in which X. *cheopis* predominates seems fairly clear, as also does the absence of liability to such epidemics in areas where X. *astia* is the predominating rat-flea. In his promised further report we hope that Major Cragg will correlate these facts with other factors known to influence the incidence of infection—e.g., the kind of rat inhabiting the areas, the number of fleas per rat throughout the year, and the climatic conditions of temperature and humidity which influence the breeding activity of the fleas.

---

[1] *Fortschr. a. d. Geb. der Röntg. str.*, 1913, xx., 453.

[2] Brit. Med. Jour., 1920, ii., 742.

To justify the full application of statistical methods it will be necessary to make a wider series of observations under definitely chosen conditions. Large batches of fleas collected at the same time of the year, preferably during the plague season, are required and the stations selected should be within fairly narrow geographical limits. When this systematic information has been obtained Major Cragg hopes to make a further and more complete report on the subject. He points out the importance of having these rat-flea areas mapped out where X. *cheopis* or X. *astia* are respectively predominant, just as the tsetse-fly belts have been mapped out in Africa. It would. he says, be unnecessary to take elaborate and expensive measures against plague in a district where the predominant rat-fleas were not a species which acted as vectors of the infection. The significance of an imported case of plague may depend, therefore, in a large measure, on the local species of rat-fleas.

AMMONIA DERMATITIS IN INFANTS.

Dr. C. V. Cooke[1] of the St. Louis Children's Hospital, remarks that the characteristic lesions of the diaper region in infants have long been recognised and described under a variety of names. Their differentiation from syphilitic lesions was first clearly made in 1905 by Jacquet, who divided them into simple erythematous, erythemato-vesicular or erosive, papular or post-erosive and ulcerative forms, all of which are stages of one process and may coexist in the same patient. The features which distinguish these eruptions from those of congenital syphilis were shown by H. G. Adamson[2] in 1908 to be as follows: (1) limitation of the eruption to the convex surfaces of the diaper region and the absence of lesions on the face, palms, and soles, and at the anal margin; (2) absence of the coppery colour of syphilitic eruptions, and absence of other signs of congenital syphilis, such as snuffles, rhagades, and glandular enlargement; (3) variation in the course of the erythematous lesions, which frequently tend to disappear without antisyphilitic treatment. The lesions are generally regarded as identical with those due to ammonia irritation. but opinions differ as to the source of the ammonia. Leopold incriminated the soap alkali remaining in diapers from insufficient rinsing, but the usual explanation is that there is a nutritional disorder with acidosis and increased excretion of ammonia in the urine. A bacteriological study of infants with ammoniacal diapers conducted by Dr. Cooke showed that a urea-splitting organism could be isolated from the stools in a number of cases, and that the formation of the ammonia in the diapers could be prevented in all such cases by the use of an antiseptic such as mercuric chloride, which caused a prompt disappearance of the ammoniacal odour and a rapid regeneration of the skin lesions.

THE IMPORTANCE OF LACTOSE FERMENTATION.

IT is now almost sixty years since Davaine demonstrated the causal relationship of bacteria to disease, and although these years have been filled with the most active and productive research there is yet a great deal about the practice of bacteriology that is empirical. When we study the work of the systematists it is impressed upon us how imperfect the subject is, and what great lacunæ remain in our knowledge which the labours of the future will have to fill. Nowhere is this empiricism more marked, perhaps, than in classification, and where any attempt is made to reduce the multitude of forms now known in human bacteriology to a systematic basis we are confronted by a most disturbing variety of tests directed towards this end, of whose exact mode of action we are generally ignorant. It must come as a shock to a student of the exact sciences to learn that one of the most important criteria upon which the bacteriologist relies to aid him in the identification of micro-organisms is the ability of these to retain a dye after subsequent treatment with iodine and washing in alcohol. This, however, is the case; Gram's method of staining being firmly established in bacteriology as a differential criterion of the first importance. Morphology, oxygen requirements, and various biological activities, all have their place in this vexed subject, and amongst these the fermentation of sugars is of great importance. Nowhere is this more so than in the vast collection of types resumed under the coli-typhoid group, and here it is the action of the organisms upon lactose which demands most consideration. There is, perhaps, no single test in the whole field of bacteriology which gives us so much information as does the fermentation of this sugar by a member of the coli-typhoid group. By what might be almost a divine provision we possess, in lactose, a sugar whose fermentation divides these organisms into two great classes, one of which contains all the important pathogenic agents of infective intestinal diseases, whilst the members of the other group are, in the main, relatively harmless. Thus the non-lactose-fermenting group includes the causal organisms of the typhoid and paratyphoid fevers, bacillary dysentery, and acute bacillary enteritis, to mention the more important, whilst among the less notorious members are the pneumo-bacillus, the psittacosis bacillus, and various rat and mouse viruses.

The other great group, constituted by organisms which ferment this sugar, is that of *Bacillus coli* and its numerous sub-types, all of which, however, are of minor importance by comparison with the highly pathogenic species met with amongst the non-lactose fermenters. Although this line of demarcation does, in a general way, separate the pathogenic species from the non-pathogenic, yet, like most classifications in bacteriology, it is only relatively exact. There are non-lactose fermenters which are saprophytes of no greater importance than the *B. coli*, whilst others occupy a middle position; such as these are Morgan's No. 1 bacillus, which is thought to bear a relationship to enteritis, especially that of infants, but whose exact significance is still in dispute. The proteus bacilli, so active in organic putrefaction, and *B. fæcalis alkaligenes*, often a harmless saprophyte but capable of invading the blood stream and of producing a typhoid-like malady, also belong to this class. On the other side of the dividing line the colon bacilli are to a certain extent pathogenic, and play a not inconsiderable part in many intestinal inflammatory

[2] British Journal of Children's Diseases, 1908, v., 13.

" in words at length and not in marks." The Register of Apothecaries never seems to have been kept, although the Act continued in force until 1756. They took things easily in those days, for in 1784 the Irish College appointed a committee to prepare a Pharmacopœia Dublinensis, and by 1791 the book had got so far that it was ordered to be printed; by 1794 a specimen edition of 100 copies appeared, and finally on March 24th, 1806, the first Dublin Pharmacopœia made its appearance. Revised editions followed, and in 1830 the Irish College of Physicians was asked by the London College to join with it and the Edinburgh College in the formation of a general Pharmacopœia for the United Kingdom, an invitation which was refused. The last edition of the Dublin Pharmacopœia was published in 1850 under the editorship of Dr. James Apjohn; it was entirely printed in English. The imperial gallon was substituted for the wine gallon and the avoirdupois pound for the troy pound. The passing of the Medical Act of 1858 led to the abrogation of local pharmacopœias by empowering the General Medical Council to publish a Pharmacopœia for the United Kingdom, and the first British Pharmacopœia appeared in 1861.

INTERNATIONAL MEDICAL HYDROLOGY.

AN International Society of Medical Hydrology was founded at a meeting held at the Royal Society of Medicine on Dec. 9th, with a preliminary membership of 71 medical men, from 13 countries, engaged or interested in medical hydrology. Delegates from France, Italy, and Holland were present. The following were elected representatives for their respective countries :—

1. Belgium: Dr. R. Wybauw, of Spa and Brussels.
2. Czecho-Slovakia: Dr. Isidore Müller, of Carlsbad.
3. France: Dr. Paul Ferreyrolles, of La Bourboule and Paris.
4. Great Britain: Dr. Wilfrid Edgecombe, of Harrogate.
5. Holland: Prof. J. Van Breemen, of Amsterdam.
6. India: Dr. H. D. Dastur, of Baroda State.
7. Italy: Prof. Luigi Devoto, of Milan.
8. Japan: Dr. Goichi Fujiyam (subject to consent).
9. New Zealand: Dr. Arthur Herbert.
10. Norway: Dr. T. W. Knudtzon, of Larvig Bad and Christiania.
11. Switzerland: Dr. de la Harpe, of Lausanne.
12. United States of America: Dr. Guy Hinsdale, of Hot Springs, Virginia.

These will collate and present to the Society, by means of an International Journal, the clinical and experimental work in each country bearing upon the medical action and uses of waters and baths. Dr. C. W. Buckley, of Buxton, and Dr. Ferreyrolles, of La Bourboule, were elected hon. editorial secretaries, and Dr. R. Fortescue Fox president.

THE house and library of the Royal Society of Medicine will be closed from Friday, Dec. 23rd, until Tuesday, Dec. 27th, both days inclusive.

THE last of the South African soldiers who were wounded in the war will shortly be repatriated; and, in view of this, the High Commissioner for the Union of South Africa, at the request of his Government, has addressed to the Army Council an appreciation of the skill, care, and attention accorded to all such soldiers in auxiliary and other hospitals in the United Kingdom during the war. As most of the hospitals have now been closed and their staffs dispersed the Army Council is making public announcement of this appreciation in the hope that it will be brought to the notice of all concerned. In acknowledging the letter of the High Commissioner, the Army Council has taken occasion to convey to the South African Government, through the High Commissioner, an expression of its gratitude for the care and attention bestowed on sick and wounded British troops while in hospital in South Africa.

Public Health Services.

WILLESDEN MUNICIPAL HEALTH SERVICE: MEETING OF RATEPAYERS WITH LOCAL PRACTITIONERS.

THE executive committees of the three Willesden Ratepayers' Associations (Kilburn, Kensal Rise, and West Willesden) met the Willesden doctors, whom they had invited individually, in the St. Andrew's Church Hall, Willesden Green, on Wednesday, Dec. 7th. Over 70 were present. Mr. Blaxland, of the Willesden Ratepayers' Association, occupied the chair.

The Chairman, after explaining that the occasion was the outcome of the proposed meeting with the B.M.A. division, called attention to the great extension of health services contemplated in the forty-fifth annual health report to the Willesden U.D.C. (Appendix M.), which he characterised as unnecessary seeing that the hospitals of London are still, as always, open to Willesden patients. He called upon Dr. G. W. R. Skene to speak to the memorandum[1] issued by the B.M.A., Willesden division, criticising the health policy of the Council.

Dr. Skene, candidate for the Willesden Council at the next election in April, said that doctors were not opposed to public health, but they wanted it carried out properly, with a good return for the money spent. He emphasised the neglect of medical inspection and preventive work generally by a public health staff which tried to do the work of the general practitioner. The health report was itself a condemnation of the whole service. He gave instances of interference by health visitors in the work of general practitioners. A municipal hospital should, he said, be a model hospital; the Willesden hospital should be used for the purpose for which it was intended, which would give the staff a chance to do their work properly; at present they were most unfairly handicapped. He and his colleagues were willing to assist in every possible way with the health work of the district if they were allowed to do so, as well as to consult and advise the health committee of the Council.

Dr. W. Lock, another prospective candidate, said that the health report condemned the service as inefficient and wasteful, and showed it to be a danger to the community. Preventive work should come first and not be impeded by treatment largely carried out by unqualified persons. He hoped the ratepayers would put a stop to the wholesale giving away of things for nothing, a gift which did not tend to improve the race or to strengthen the character.

A ratepayer suggested a petition to the Ministry of Health for a full inquiry.

Dr. H. J. Macevoy said the way to deal with the matter was to return men at the next election who would take the proper steps. The Ministry of Health had made objections already to the expenditure, and no doubt other objections would follow. The Willesden health department failed, he said, to provide proper preventive measures or to deal with epidemics effectively. The general practitioner was the supporting pillar in treatment; he first saw the case, and he knew the people and the house conditions. But instead of being asked to coöperate he was ignored in the report as a person of no consequence. It was difficult for doctors to serve on the Council, but there was no reason why they should not be coöpted on the health committee for purely consultative purposes, when they would willingly give their advice. Treatment at clinics was, he said, unnecessary, as it could be more cheaply and better carried out by private practitioners in the district.

Dr. W. W. Stocker, who was chairman of the health committee 20 years ago when the hospital was built, said that probably a small extension of the hospital was necessary for infectious diseases. School teachers, he said, were against the clinics as interfering with their work. He thought much of while the total ordinary policies showed a mortality of 70 per cent. During the second year, while the total mortality remained the same, the mortality on the lives examined increased from 39 to 47 per cent. It appears, therefore, safe to conclude that "the benefits of the life extension examinations are pretty well limited to the years immediately following the examinations, and run out at the end of about five years." Dr. Knight's report goes on to show that the company in paying for these examinations has had its principal returned, and has made a 200 per cent. profit on the investment, during a period of approximately five years. This is on the assumption that the subsequent experience on these lives does not exceed the experience expected according to the American Men Table.

---

[1] THE LANCET, Nov. 26th, p. 1121.

Dr. Knight points out in conclusion the reservations needed in arriving at even tentative inferences. They are reservations common to nearly all attempts to measure statistically the effect of social measures. The results do not, nor could they, allow for the factor of self-selection. The group of policy-holders reported on elected to be examined, sought out the opportunity to be examined, and returned periodically for examination, even though many of them showed no serious impairment. These facts denote that they were persons taking their health seriously, and who, apart from medical examination, would be likely to adopt measures to protect their health. In these respects there may have been initial bias in the special group which colours the general results, and it is not possible to measure the effect of this fact. But we may agree with Dr. Knight that it probably does not negative the highly favourable results shown. On the whole the experiment has been of great value, and even if the extent to which money has been saved by the examinations and action taken on these cannot be fully demonstrated, the system itself is likely to appeal to the insured person as well as the company, and may be imitated in other countries.

MEDICINE IN ART.

ACCORDING to Sir Berkeley Moynihan, who discoursed on "Medicine in Art" to a social gathering of Fellows of the Royal Society of Medicine and their friends on Dec. 7th, the proverbial hideousness of gargoyles was merely an exaggerated portrayal of abnormal conditions. The celebrated gargoyle of the church of Santa Maria Formosa, at Venice, erroneously described by Ruskin as "leering in bestial degradation" typical of the evil spirit of Venice in the time of her decadence, was immediately recognised by Charcot as the facies of hystero-epilepsy. This was the condition so frequently described and depicted in the Middle Ages as of one "possessed of evil spirits," the exorcism of which was the subject of many pictures by the old masters. The attitude of the victim, characteristic of hystero-epilepsy, was more or less accurately portrayed in many celebrated pictures—for example, Reuben's "Transfiguration," in which the boy "possessed of evil spirits" was drawn with spine arched backwards, forearms flexed and pronated. and hands firmly clenched. Sir Berkeley Moynihan showed pictures in which the artist had exhibited great anatomical knowledge in the portrayal of emotions. Sir Charles Bell, the medical artist, had drawn the face of the father in the Laocoon when he wished to portray "anguish and the sense of impending death." Many diseases only recently recognised had long been recorded in art. The Egyptian god, Ptah, whose images date back to 3000 B.C., was a typical achondroplastic dwarf, and so also was the god Bess, who presided at births. In the Bayeux tapestry Turold, the horse-holder, was an achondroplasiac, and many pictures, such as Velasquez's "Antonio the Englishman," showed achondroplastic dwarfs in charge of animals. Deformities, such as talipes equinovarus and genu recurvatum, were represented in early Egyptian art, while the bust of Æsop showed the angular curvature of Pott's disease. Early Roman bronzes even portrayed the condition of hydrocephalus. One of Holbein's canvases was a faithful reproduction of rhinophyma. The late Sir Spencer Wells had always said that the famous portrait of Mary Tudor depicted the typical facies of a woman with an ovarian cyst. The craft of the surgeon was also represented in art—the operation most frequently portrayed being circumcision. Sir Berkeley Moynihan showed a picture of the removal of a sebaceous cyst by a surgeon whose diploma hung on the wall behind the patient, while he carried another in his hat. A picture in the Sistine Chapel depicted the first woman surgeon performing circumcision, while another, by Moroni, even showed an early appliance for dropped-foot, the result of a wound of the external popliteal nerve.

The address was learned, amusing, and suggestive, and was very highly appreciated by the audience.

HYGIENE BY EXAMPLE.

A SOCIETY, entitled L'Hygiène par l'Example, has been formed in France, with Mr. Léon Bourgeois, former President of the Republic, as its first president, Dr. Marchoux, professor at the Pasteur Institute, as general secretary, and Mme. Léon Mazart as assistant secretary. As its title implies, the object is not to deliver lectures or distribute pamphlets but to preach by example. Therefore, wherever its members can obtain admittance they endeavour to introduce some modification that will tend to improve the health of those concerned. In rural districts especially, and in elementary schools, there is much need of sanitary improvement. Thus, for example, a boys' school was discovered with no water-supply and no washing accommodation. Thereupon a hose and pump was installed at the communal wells, and the boys were drilled in pumping water to the school and in giving themselves a thorough wash every day. Then, again, in Paris there is a school for weakly girls in the rue des Épinettes, a crowded neighbourhood. Thereupon the society arranged for a class-room to be built near, at the fortifications in the Boulevard Bessières, where there is a large expanse of open air hard by. The room was well heated and well ventilated, care being taken to distribute the cold air as it entered and prevent any direct draught. In summer lessons are given in the open air and the pupils exposed as much as possible to the direct rays of sunlight. They are all carefully washed and abundantly fed. Statistics are published setting forth the increased height and chest measurements resulting from all this care, and this is truly termed a practical demonstration of hygiene by example. There may be many occasions in Paris and elsewhere when outside help or advice supplies the final stimulus necessary to action, and thus a long meditated reform is realised.

THE INTERNATIONAL STANDARDISATION OF SERA.

AT the conference which was started by permission of the Government at the Ministry of Health on Monday afternoon last, the President of the Health Committee of the League of Nations, Prof. Madsen of Denmark, presided. The various countries whose leading workers in serological problems had been invited to attend were enumerated in our columns last week, and the following is a list of the corresponding delegates.

Austria: Dr. R. Mueller, Professor of Serology at the University of Vienna.

Belgium: Dr. Renaux, Deputy Director of the Pasteur Institute at Brussels.

France: Dr. Louis Martin, Sous-Directeur de l'Institut Pasteur, Paris; Dr. Dopter, de l'Institut Pasteur, Paris; Dr. Cotoni, de l'Institut Pasteur, Paris.

Germany: Prof. W. Kolle, Geheimrat, Director of the Institute of Experimental Pathology, Frankfort; Prof. H. Sachs, Director of the Cancer Research Institute, Heidelberg.

Great Britain: Sir Frederick Andrewes, M.D., F.R.S.; Dr. H. H. Dale, F.R.S.; Prof. W. Bulloch, M.D., F.R.S.

THE WAR EMERGENCY FUND.

A MEETING of this Fund was held at the rooms of the Medical Society of London on Dec. 7th, under the presidency of Sir A. PEARCE GOULD, the Hon. Chairman. Letters of apology for inability to attend the meeting were announced from Sir THOMAS CLIFFORD ALLBUTT, Sir CHARLES BALLANCE, Dr. A. LYNDON, Sir DONALD MACALISTER, Sir ARTHUR MAYO ROBSON, and Sir JOHN LYNN-THOMAS.

The general report of the work of the War Emergency Fund from 1916 to 1921, which was read by Dr. G. NEWTON PITT, the hon. secretary, stated that the War Emergency Fund was inaugurated by the Royal Medical Benevolent Fund in order to help medical men who, by leaving their practices and taking up commissions in the R.A.M.C., found themselves in temporary difficulties which, it was anticipated, would become more general on demobilisation. Applications for help amounting to about £20,000 were received and grants had been made to 134 medical men. In nine cases these had exceeded £300 and in four of them £400, and had been spread over several years. In 27 cases the grants were between £200 and £300, in 51 between £100 and £200, and 47 were for small amounts. The money had been used also, to enable officers to complete the purchase of practices and equipment, to clear off accumulated debts, and to educate children. Many of the cases were those of men broken down in health through the war. At the present moment 47 boys and girls were being educated. In several cases this education would be continued till the age of 16 or later, and some cases were being helped at medical schools and at universities. The main use of the Fund during the next few years would be to carry on educational work and to assist those medical officers who had returned to civil work with health so impaired that they were unable to earn sufficient income.

The treasurer's report of Sir CHARTERS SYMONDS showed that the receipts, including subscriptions from the profession £22,356 3s. 6d., donations from National Relief Fund £10,000, together with interest on investment and on deposit account, amounted to £35,619 1s. 5d. The expenditure in grants was £20,102 3s. 1d., with working expenses £1937 13s. 1d., amounting to £22,039 16s. 2d. The sum in hand at the present moment was £13,579 5s. 3d. The grants, said Sir Charters Symonds, had taken two forms, the one to relieve immediate necessities, and the other to educate children. The latter would involve an expenditure extending over some years and would probably absorb nearly £10,000. If the children were educated up to the end of the sixteenth year he estimated that the Fund would have something like £4000 left for distribution.

Sir A. PEARCE GOULD, in proposing that these reports should be adopted, referred to the great services which had been rendered to the Fund by the late Dr. Samuel West, who had laid its foundations and to whom by his foresight and energy the success of the Fund had been largely due. He thanked the medical and lay press for the material help which they also had rendered. Results had shown both that the Fund was needed and that great need had been met. He hoped that the children who were being looked after by the Fund would have their education extended beyond the sixteenth year.

Dr. HERBERT SPENCER said that the reports were extremely satisfactory, and he agreed that the education of the children should be prolonged.

Sir D'ARCY POWER suggested that in many cases it might be advisable to apprentice the children, as they might not be in a position to take advantage of extended educational courses.

Sir THOMAS BARLOW said that the Fund had accomplished a very important, onerous, and responsible piece of work. He fully sympathised with the idea of extending the educational facilities, but expressed the wish that the treasurer would supply details of how this could be accomplished.

The reports were then adopted.

DENTAL BOARD OF THE UNITED KINGDOM.

THE first session of the Dental Board was opened on Dec. 7th, at 44, Hallam-street, W., the Rt. Hon. FRANCIS DYKE ACLAND, M.P., being in the chair. The names of the members of the Board are given below; all were present with the exception of Mr. J. Sinclair, who was prevented from attending by illness.

Chairman (appointed by the Privy Council): Rt. Hon. Francis Dyke Acland, M.P.

Three members not being registered medical practitioners or registered dentists: Laurence George Brock, C.B., appointed by the Minister of Health; Dugald M'Coig Cowan, M.P., appointed by the Scottish Board of Health; John Sinclair, D.L., appointed by the Lord Lieutenant of Ireland.

Three members appointed by the General Council: Holburt J. Waring, F.R.C.S., member of the Branch Council for England; Sir James Hodsdon, K.B.E., F.R.C.S.Edin., Member of the Branch Council for Scotland; Sir Arthur Chance, F.R.C.S. Irel., member of the Branch Council for Ireland.

Six members who are engaged in the practice of dentistry: Fred Butterfield, appointed by the Privy Council; Horace Archibald Robertshaw, appointed by the Privy Council; William Henry Dolamore, M.R.C.S., L.D.S., appointed by the Minister of Health; William Henry Gilmour, M.D.S., appointed by the Minister of Health; William Guy, F.R.C.S., L.D.S., appointed by the Scottish Board of Health; Edward Leo Sheridan, F.R.C.S., L.D.S., appointed by the Lord Lieutenant of Ireland.

Mr. Norman King was appointed Registrar of the Board.

Chairman's Address.

The CHAIRMAN in his opening address sketched the history of dental administration from its inception in the middle of last century to the passing of the Dentists Act, 1921.

Standing Orders: Appointment of Committees.

The Board then proceeded to consider its Standing Orders, which have been based upon those of the General Medical Council, and to make such alterations in their details as appeared necessary.

The following committees were then appointed:—

Business.—Mr. Brock, Mr. Dolamore.

Discipline.—Mr. Butterfield, Mr. Sheridan, Mr. Gilmour, Mr. Brock, Mr. Robertshaw, Sir J. Hodsdon, Sir A. Chance.

Registration.—Mr. Butterfield, Mr. Sheridan, Mr. Guy, Mr. Gilmour, Mr. Robertshaw, Mr. Waring, Mr. MacCowan.

Education or Examination.—Mr. Guy, Mr. Sheridan, Mr. Gilmour, Sir J. Hodsdon, Mr. Robertshaw.

Students' Registration.—Mr. Sheridan, Mr. Gilmour, Mr. Dolamore, Sir A. Chance, Sir J. Hodsdon.

Finance.—Mr. Brock, Sir J. Hodsdon, Sir A. Chance, Mr. Dolamore, Mr. Waring.

One of the early functions of the Finance Committee will be the consideration of a site for the Board's future offices.

Appointment of Treasurer and Trustees.

The following were also appointed:—

Treasurers.—Mr. Waring, Mr. Dolamore.

Trustees.—Mr. Waring and the present trustees of the General Fund.

The Board considered that three trustees might prove a better number than two, in view of the possibility of two trustees dying at the same time.

The above appointments having been made, the Board proceeded to frame regulations and to consider the other subjects on the agenda paper in camera.

THE EAST FORTUNE SANATORIUM.—At a meeting of Hawick Town Council a report was submitted of the probable expenditure to be incurred in connexion with the East Fortune Sanatorium. The buildings were found to be in good condition and to require little alteration. The most costly improvement necessary was the installation of a central heating system to conform with the Board of Health regulations. As the buildings stretch for about half a mile this involves heavy expenditure. In order to obtain the Government grant of £180 per bed, the plans must be prepared and submitted to the Board of Health before the end of March.

the patient remained free from pain and was able to live a normal active life. Prof. Jonnesco is to be congratulated on this his second successful operation for angina pectoris. Whether a nerve such as this would be accessible to alcohol injection is a point which might be put to the proof, but the course of the sympathetic may be too near important vessels and ducts to render such a simple procedure feasible.

THE ASSOCIATION OF TYPHUS VIRUS WITH BLOOD PLATELETS.

Starting from Charles Nicolle's statement that the leucocytes are the principal if not the only elements in the blood capable of transmitting the virus of typhus fever, Dr. J. Ségal has recently performed a series of experimental investigations in the bacteriological department of the Lister Institute into the site of the virus. Assuming that Nicolle's statement is true, Dr. Ségal argues that it should be possible to obtain the virus in a concentrated form by producing a leucocytic exudate in infected animals. Guinea-pigs which had been infected with the typhus virus were given intraperitoneal inoculations of sterile broth on different days of the disease, and the peritoneal fluid was withdrawn three to five hours later. In no case did the inoculation of leucocytes from 4–5 c.cm. of the exudate (containing over 50,000 leucocytes per c.mm.) produce infection in guinea-pigs, whereas the blood and the brain from the same animals were shown to be infective. The work of Kusama, who claims to have demonstrated an intimate connexion between the platelets and the typhus virus in the blood stream, suggested experiments on guinea-pigs which, in Dr. Ségal's opinion, have given complete confirmation of these findings.

The plasma obtained cell-free by prolonged centrifugation of citrated blood proved non-infective in doses of 5–6 c.cm., whereas the inoculation of platelets invariably produced infection even with such a small quantity as could be obtained from 1·5 c.cm. of blood. Thus, by the separation of the platelets from virus-containing blood a high concentration of the virus can be achieved. With this virus it has been found possible to infect a guinea-pig by the inoculation of a small quantity into the anterior chamber of the eye, and by intra-testicular injection. It has also facilitated the experimental infection of lice (*Pediculus humanus*) conducted by Dr. Ségal jointly with Mr. A. W. Bacot. The method used was the injection per rectum of the platelet layer of centrifuged blood from typhus-infected guinea-pigs, and subsequently the re-passage of the virus from these lice into other guinea-pigs.

At a recent laboratory meeting of the Pathological Section of the Royal Society of Medicine Mr. Bacot gave a fascinating demonstration of the technique adopted by him, following the method described by Weigl,[1] of feeding lice infected with the virus of typhus fever by rectal injection. The alimentary tract of lice is normally sterile, and experience shows that its contamination with bacteria results in the speedy death of the insect: it is therefore necessary to adopt measures to avoid the contamination of the gut when feeding by the rectal passage. After two to four minutes immersion in 2 per cent. lysol Mr. Bacot transfers the lice to sterile water and thence removes them to filter-paper placed in Petri dishes to recover. To inject the meal of whipped human blood the louse is held under a slip of paper on a glass slide placed on the stage of a binocular dissecting microscope (about 16 diameters magnification) with its anal segments projecting beyond the paper slip. A finely-drawn capillary pipette, the end of which has been smoothed by flaming, is inserted a short distance up the rectal passage and sufficient blood to fill the stomach is forced up by means of a rubber teat. The pipette is washed out after each injection and then sterilised in boiling water before taking up the blood for the next injection. The skin and hairs surrounding the rectal opening of the louse are treated with a minute drop of 85 per cent. alcohol immediately prior to the insertion of the pipette. Two meals per day are necessary if the insects are to be incubated at 32° C. (90° F.). Lice have been successfully fed by this method for 22 days. Following this technique female specimens of *Pediculus humanus* were given an initial meal of the platelet layer of the centrifuged blood of typhus-infected guinea-pigs, and thereafter fed by injecting whipped human blood. Microscopic examination showed slight infection of the cells of the gut with *Rickettsia prowazeki* as early as the fourth day following the infecting meal, and very heavy infection within 8 to 12 days. The insects were kept for the most part at 32° C., two or more days being passed at room temperature (about 18° C.) in each week. Seven out of nine guinea-pigs inoculated with the emulsified guts or ovaries of platelet-infected lice showed temperature curves of the usual typhus character. One of the guinea-pigs which did not react failed to respond to a subsequent heavy injection of the emulsified brain of an infected guinea-pig; the other showed an abnormal temperature curve, and the question of typhus infection in this guinea-pig therefore remains in doubt. The time occupied in development was only slightly more than half of that required for an equivalent development in lice fed upon typhus-infected monkeys or when whole blood from an infected guinea-pig was injected.

THE DUBLIN PHARMACOPŒIAS.

Pharmacopœias are always interesting works, although the early specimens are far more romantic than the modern, which are strictly scientific and business-like. Attempts were made quite early in medical history to secure the purity of drugs and medical preparations. For instance, in the Kingdom of Sicily, under that enlightened monarch Frederick II. (1194–1250), apothecaries were under oath obliged to compound their preparations " secundum predictam formam." How complicated some of these preparations were may be gathered from a perusal of the poem of Gilles de Corbeille (1140–1224), " De Laudibus et vir tutibus compositorum medicaminum." Even as late as the seventeenth century, and onwards up to 1721, the London Pharmacopœia afforded good reading as to its remarkable compound preparations, and not until 1746, when the fifth London Pharmacopœia appeared, was there a break with the old traditions. The first London Pharmacopœia was published in 1618, and the first Edinburgh one in 1699, but, says Dr. Percy Kirkpatrick in his interesting paper on the Dublin Pharmacopœias now before us, " nothing of the kind had been done in Ireland." In 1719 the Fellows of the Irish College of Physicians came to the conclusion that Ireland should have a pharmacopœia of her own, and Dr. Cuming was asked to prepare a rough draft of the medicines " that he thinks proper for a dispensatory." Nothing seems to have come of this proposal, and when the London Pharmacopœia of 1721 appeared the Irish College of Physicians agreed to recommend to the Dublin apothecaries to use this work until their own was perfected. So matters went on until 1727 when a committee was appointed to " prepare the dispensatory." The committee, however, did not produce any report, and did not even resort to that favourite plan of committees, the appointment of a subcommittee, so the next move was made in Parliament. In 1735 an Act was passed for preventing frauds and abuses in the manufacture, preparation, and selling of drugs; visitors to inspect apothecaries' shops were appointed; a register of apothecaries was made compulsory, every physician or surgeon prescribing drugs had to sign his prescription with name or initials, and was also to express the quantities of the drugs prescribed however, on good authority that this case was not cholera. Active precautions are everywhere being taken, and sanitary and municipal authorities are displaying a laudable vigilance. Matters are different in the interior of Russia. From the districts about Moscow have come reports concerning the epidemic—reports of 300 to 500 deaths per day in one province alone, of hospitals full of cholera patients, and of chemists' shops devoid of the most indispensable drugs. Moreover, the population is in a condition of semi-starvation, food being so scarce that families can afford only one meal a day. Infants are dying for lack of milk, and pregnant women are completely unable to feed themselves properly. The medical staff of the hospitals is very deficient in strength and inferior in quality; the former doctors have been expelled as counter-revolutionaries and their successors are graduates of recent qualification at universities where the chief subjects are "socialism and communism," anatomy and physiology being of second importance. Prof. Pavlov, the world-famed physiologist of the University of Petrograd, has been expelled from the University, and is said to be nearly starving. In such conditions it is not to be wondered at that cholera claims thousands of victims; other infectious diseases are also flourishing, threatening the sanitary condition of the whole of Europe.

SWITZERLAND.

(FROM OUR OWN CORRESPONDENT.)

Reform of the Medical Curriculum.

THE reform of the medical curriculum has been for some time the subject of discussion, and a commission chosen by the Federal Department for the Interior is still deliberating on this question. One of the chief problems under consideration is the standard of the entrance examination. So far Latin has been compulsory for the "Maturität" (or "Maturité") examination, and Greek optional, being interchangeable with a modern language—preferably English. The majority of our medical men have had a classical training, and there is now a movement tending to replace the classics by a thorough course in the natural sciences. The Executive of the Medical Association thought it wise to test the opinion of the profession on this question, and a questionnaire was sent out with the following results:—Is it advisable to require the same "Maturité" for the medical and technical profesions?—85 Yes, 1542 No. Do you think that the study of Latin is necessary for the prospective medical man?—1583 Yes, 69 No. Is it advisable to make Greek compulsory again?—963 Yes, 651 No. Do you consider a "Maturité" requiring natural sciences, the mother language, and mathematics, sufficient for the prospective medical man?—50 Yes, 1591 No. These figures are interesting, since they show clearly that the great majority of the profession in Switzerland sticks to the ideal of a classical training. Perhaps a few years ago the vote would have been different. To-day it is realised more clearly that the profession can only retain respect when the members have a wide and comprehensive education, and that a purely technical training does not suffice to make a good doctor.

Cocaine.

A sad chapter is the cocaine mania which seems to be in full swing in some of our towns. The cause may be chiefly economic, since most of the cocaine is imported from Germany at very moderate prices owing to the high Swiss exchange. The price paid for one kilo is said to be varying between 700 and 1000 francs, and those who traffic in the drug sell it to their clients for 5 to 20 francs a gramme. Usually it is sold adulterated with boric acid, sugar, and similar compounds. Unfortunately we have no adequate legal means of dealing with this abuse. At the annual meeting of the Société Suisse de Psychiatrie on Nov. 27th a resolution was passed urging the Federal Council to take immediate and energetic steps to stamp out the contraband and illicit traffic of cocaine and to enforce a law under which cocaine maniacs, each of whom is a source of contamination to his environment, can be speedily interned.

Felix Lewandowsky and Albrecht Burckhardt.

The Faculty of Medicine of Basle mourns the loss of two distinguished members. Dr. Felix Lewandowsky, professor of dermatology and director of the Clinic for Skin Diseases, has died at the early age of 43. Prof. Lewandowsky, who came originally from Hamburg, underwent training at the dermatological clinic of Berne under Prof. Jadassohn. His studies on tuberculosis of the skin, which he embodied in a brilliant monograph, brought him into prominence. As a lecturer he was distinguished by clear and precise exposition and vivid diction.

Dr. Albrecht Burckhardt, professor of hygiene for 30 years, was a relative of J. L. Burckhardt, the famous orientalist. He was a fine example of the old school of culture and a true son of his native city of Basle, to which he devoted all his energies. In 1909 he published what may be called his life work: Demography and Epidemiology of the City of Basle from 1601 to 1900. Few continental towns offered better possibilities for such a study. Most Swiss towns, with their large stable populations, have well-kept archives. At Basle, which has had a university since 1460, there exist also records and notes on the state of health and current epidemics by reliable physicians. Burckhardt, who had a strong bias towards historical research, made the best use of all these opportunities, and produced a work which is in some ways unique. He was also the author of a biography of Paracelsus. Dr. Burckhardt was a well-known figure in Basle, and his death is a loss to the whole community.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Notification of Infectious Diseases and Statistics.

AT a recent meeting of the Société de Médecine Publique et de Génie Sanitaire Dr. P. Paquet, chief medical officer of health for the département de l'Oise discussed the results obtained in this county in the course of the last ten years. During this period medical practitioners have notified 19,771 cases of infectious diseases, the population consisting of 387,760 inhabitants. The cases of typhoid fever numbered 1207; though the total yearly number of infectious diseases notified has not varied much. cases of typhoid fever appear to have greatly decreased since 1914; in 1911 there were 271 cases, and in 1920 only 52. Dr. Paquet pointed out that most cases occurred amongst the people living in the valleys, where the water in the wells is rather shallow; in districts where the depth of the water in the wells is 20 metres or more typhoid fever is only exceptionally recorded. It is interesting to note that the progressive diminution of the yearly number of cases of typhoid fever in the département de l'Oise continued to take place during the war, though a great many troops were concentrated in its area and in spite of the fact that refugees crossed the county in great numbers on several occasions. According to Dr. Paquet, this is due to the fact that inoculation against typhoid fever has been practised on a large scale amongst the civilian population of the county; he also points out how the water-supplies have been constantly improved during the last ten years, and mentions the educational influence of the medical officers. During the same period 2041 cases of diphtheria have been notified. The number recorded annually remained approximately the same until 1915, since when there has been a progressive increase. Dr. Paquet pointed out that these unsatisfactory statistics are not peculiar to the département de l'Oise; similar facts have been recorded throughout France. It has been found in the département de l'Oise that the disease is more the work for poor children should be done by the district medical officer of the Guardians; he had been one of these for 20 years.

Mr. Weaver (Kensal Rise Association) said that they had been waiting for years for enlightenment on health methods, and he was glad that they had got it at last. With the help of a sympathetic majority in the Council, an ambitious medical officer of health had gone far beyond his proper sphere. The remedy was in the hands of the ratepayers, who should remove those responsible for the present policy. He hoped doctors would continue to meet and assist them with advice on health matters.

Dr. J. B. Dunning referred to the non-infectious cases in hospital, most of whom could have been treated at home. He thought that no one need suffer even if the hospital was not extended.

Dr. C. F. T. Scott, chairman of the B.M.A. division, proposed a vote of thanks to the chairman. He pointed out that a local advisory council, as suggested in the Dawson report, would go a long way to put health matters on the right lines.

Dr. Skene, in seconding the vote of thanks, informed the meeting that Mr. A. W. Bourne, one of the medical specialists to the Urban Council, had resigned as he did not approve of the Council's policy.

The Chairman, in reply, invited the doctors to appoint three or four of their number to coöperate with the Ratepayers' Associations, the political associations, and other bodies in selecting candidates, in order to avoid overlapping.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

BIRMINGHAM.

Dr. John Robertson, in submitting his report for 1920, says that 1920 was probably the best on record as regards statistics, and that there is every indication that the slow process of spreading knowledge as to how to prevent disease or how to maintain good health is bearing fruit. He considers that the outstanding difficulty in health work at the present time is the inability to provide decent homes for the large number of people who are now sufficiently educated to make proper use of them. Dr. Robertson estimates the population for 1920 at 910,000. The marriage-rate was 16·6, similar to pre-war years. The birth-rate was 27·6, the death-rate 12·6, the infant mortality-rate 83, and the tuberculosis death-rate 1·10. There was great pressure on the hospital accommodation in the matter of isolation wards, and Dr. E. H. R. Harries gives an account of an interesting and successful experiment in "bed isolation" for the purpose of avoiding cross infection, in imitation of the scheme worked out ten years ago by Dr. C. Rundle at one of the Liverpool hospitals. Diphtheria was very prevalent in Birmingham during 1920 and caused 201 deaths; Dr. Robertson is evidently of opinion that antitoxin is not used early enough and also not in sufficiently big doses in severe cases. Both notifications and deaths from pulmonary and non-pulmonary tuberculosis were lower than ever before. The register is carefully kept, and there were at the end of 1920 15,709 names thereon; these are visited by 16 tuberculosis visitors. There were 132 shelters loaned out at the end of the year.

Mr. Brennan De Vine, veterinary superintendent, reports that during the year 21 herds, comprising 596 cows, were being dealt with under the scheme for the eradication of tuberculosis from dairy herds by means of the tuberculin test. The cost of this work during the year was £126, £20 being for tuberculin and the remainder for veterinary fees and expenses. The value of the money spent on child welfare work in Birmingham (£16,586 for 1920) has recently been questioned, and Dr. Robertson in defending the expenditure states that not only has the infant mortality-rate been halved in Birmingham since 1900, but the health of the surviving children has also been "enormously" improved. Birmingham is second only to Bristol among the largest towns in respect of infant mortality-rate. To those who suggest that climate is the cause of the improvement, Dr. Robertson points out that the reduction in mortality from causes other than diarrhœa and enteritis has been almost as great as that in the total infant mortality. The need for the separate cot for the baby is shown by 27 deaths from "overlaying." In all but two cases the parents were said to be respectable and sober persons, but a disproportionate number of the cases occurred on the nights following holidays. The death-rate from this cause is only one-fifth of what it was in 1900–5 and went down with a sudden drop in 1916. Notifications of ophthalmia neonatorum numbered 444; 34 were severe cases, the eyes being permanently damaged in 10 of these, 4 being practically blind in both eyes, while of the remaining 6 had normal vision in one eye.

Birmingham has the same story to tell as other places as regards failure to persevere in treatment for venereal disease. Dr. Robertson gives the figures for two of the hospitals: 1. New cases treated—gonorrhœa, 1327; syphilis, 1077. 2. Ceased to attend before completion of treatment (old and new) gonorrhœa, 602; syphilis, 438. 3. Ceased to attend before final tests—gonorrhœa, 782; syphilis, 720. One in every 11 deaths was due to cancer and the number of deaths from this cause has gone up steadily from 748 in 1911 to 1014 in 1920. The death-rates from bronchitis and pneumonia in Birmingham have fallen and are now nearly as low as the figures for the whole of England and Wales.

BOURNEMOUTH.

Dr. A. D. Edwards reports that Bournemouth has been free from serious epidemics during the year and that the zymotic death-rate has been one of the lowest in the country. The estimated population for 1920 was 85,919. The birth-rate was 16·34, the death-rate 11·10, the infant mortality-rate 45·39, the death-rate from pulmonary tuberculosis 1·02, and from other forms of tuberculosis 0·15. Of the 954 deaths, 127, or about 1 in 7½, were due to cancer and 147 from organic heart disease. The death-rates from these causes are no doubt to some extent swelled by the reputation of Bournemouth as a resort for invalids. The maternity and child welfare work has increased and is aided by voluntary workers. The Boscombe Day Nursery was taken over for a time by the sanitary authority and closed in January, 1921. The sanitary authority use beds at the National Sanatorium, Bournemouth, and other sanatoriums for early cases of pulmonary tuberculosis and beds at the Firs Home, Bournemouth, and the Borough Isolation Hospital for advanced cases. The beds at the Borough Hospital have not been fully utilised. During the year 17 children were sent to the Harpenden Sanatorium, but no provision is made by the sanitary authority for surgical tuberculosis. Dr. Edwards points out that patients after a few months at a sanatorium want to go home and are usually unwilling to go on to a farm colony; nor does he think that consumptives with their families would be willing, as a rule, to move into village settlements if such were available. Sixty-three new cases of syphilis attended the V.D. clinic and 43 patients ceased to attend without completing treatment. The corresponding figures for gonorrhœa were 80 and 52. The figures for milk adulteration are high. Of 157 samples 5 were deficient in milk fat and 12 contained added water, the added water percentage in 3 of the samples being 49·4, 29·7, and 24·4 respectively. Ten out of 31 samples of cream (not sold as preserved cream) contained boric acid and the public analyst comments adversely on this fact.

BRISTOL EYE HOSPITAL.—At a recent meeting of this hospital it was decided to follow the example of the two general hospitals of the city, and to collect payments from both out-patients and in-patients, in the latter case up to £1 1s. per week, as contributions toward the cost of maintenance. Mr. Edmund King, the chairman, said that this scheme was not put forward as a real settlement of the financial difficulties of the hospital, but merely as a temporary and partial relief. He went on to advocate a policy of hospital amalgamation in Bristol as the only alternative to State control. During 1919 and 1920 this policy was discussed at length by representatives of the principal hospitals in the city, but no actual steps were decided upon.

THE WOOD-HILL FUND.

THE following subscriptions and promises have been received to the fund for reimbursing Dr. H. Wood-Hill in the very heavy expenses incurred by him in the case Clayden *v.* Wood-Hill, in addition to those recorded in the list published in our issue of Dec. 3rd (p. 1187). There is ample need for further support.

EPSOMIAN CLUB: ANNUAL DINNER.—Dr. H. E. Haynes presided at the annual dinner of the Club, held at the Trocadero Restaurant on Dec. 8th, when there was a full attendance of old Epsomians, largely medical, a few clerical, with representatives of other professions. Sir Ernest Pollock, Sir D'Arcy Power, and Sir J. Purves Stewart were among the invited guests. "Floreat Epsomia" was sung with enthusiasm after the headmaster, Rev. W. J. Barton, had chronicled the last year's school activities. Dr. H. F. Ealand, of Farnham, wittily proposed the guests and Sir D'Arcy Power voiced the warm feelings of those present towards the chairman for his many services to the Royal Medical Foundation.

"Audi alteram partem."

CLINICAL UNITS.

To the Editor of THE LANCET.

SIR,—It has been a great satisfaction to me to find that my reflections[1] on this new development of medical education in England have been well, even *cordially, received; but no doubt*, as time goes on, certain just criticisms will appear. Meanwhile my notions may be on right lines, in the main. One criticism, which has appeared more than once, is that, in urging that the direct function of the director of the unit will be less the *teaching* of the undergraduate and more the study of disease in association with senior and graduate students, I had forgotten the counsels of Huxley and Foster that it is particularly the function of the professor to teach the beginner so that in the first instance he may get his head put straight. May I suggest that in my article I indicated—indirectly perhaps—that the conditions of comparison in this case were not the same. I said plainly that the director of the unit was but one of the teaching staff; that on the honorary staff of a large hospital there were other physicians and surgeons of even greater experience and sagacity who were at least as *well fitted to teach the undergraduate*; *in a sense* perhaps more so. The director I proposed was to be a comparatively young man, on his election, who would devote himself rather to research than to the pragmatics of practice, which in this stage of his education are, rightly enough, more prized by the undergraduate and his father.

I am, Sir, yours faithfully,

Cambridge, Dec. 9th, 1921. CLIFFORD ALLBUTT.

THE ORGANISATION OF MEDICAL EDUCATION.

To the Editor of THE LANCET.

> "It may be that professional preparation will divide into two courses—into a five-years' course on craft lines for the diploma of the colleges, and a university course for those who have the turn and the time for wider and deeper study; a difference which is perhaps coming about, more or less, undesignedly. In any case the universities must not trifle with their standards."—SIR CLIFFORD ALLBUTT, THE LANCET, Nov. 5th, 1921.
>
> "Is it not wasteful, archaic, not to say stupid, to insist that each and every student shall pursue precisely the same subjects, presented in the same way?"—Prof. MADISON TAYLOR, *American Medicine*, August, 1921.

SIR,—The innumerable suggestions which, within the last few years, have been made with a view to reorganisation of medical education, leave little doubt as to the existence of widespread dissatisfaction with the *present state of affairs. In every civilised country* efforts have recently been made to counteract the growing complexity of the medical curriculum by the elimination or curtailment of the least important educational subjects. In theory this process may seem comparatively simple; in practice it is reminiscent of an anecdote related by Sir Clifford Allbutt. He sat on a committee to simplify the *British Pharmacopœia by the ejection of the least* valuable of its contents. But which were they? Whenever one member of the committee proposed the ejection of a certain drug, another member would insist that this particular drug had been his chief aid and stay. So the British Pharmacopœia emerged from this ordeal as bulky as ever. As long as the problem is solely in the hands of professors and *specialists, there is little chance of a radical change for* the better in medical education, for the same pitfalls await the reformer as those which Sir Clifford Allbutt

AN EAST ANGLIAN HEART CLINIC.

THERE can be little doubt that the war caused a considerable increase in disorders of the heart, both functional and organic, amongst men who have served in the army. To deal with a large number of these cases occurring in the Eastern region, the Ministry of Pensions has recently established a series of cardiovascular clinics, with a central hospital at Norwich, in the district embracing the counties of Norfolk, Essex, Suffolk, Cambridge, Bedford, Herts, Oxford, Bucks, and Berks.

In each area a heart specialist has been appointed, who sits on the special heart boards, and has charge of the local heart clinic to which patients are sent for diagnosis and advice as to treatment. This treatment is carried out by the panel practitioners, acting under the advice and with the coöperation of the heart specialist. Dr. Hubert J. Starling of Norwich, has been appointed consulting cardiologist for the Eastern region. He has charge of the cardiovascular clinic and hospital in Norwich, with supervision of all the cardiovascular work in the other areas of this region. For the purpose of the clinic and hospital, a large house in Thorpe-road, Norwich, a private residence before the war, and formerly used as a limb-fitting centre, was adapted by the Ministry of Pensions in June, 1921. There is accommodation here for 25 in-patients, whose average stay in the institution is six weeks. The cases are sent here from all the areas in the region, either for diagnosis of obscure conditions, or for grading by means of their response to exertion, as ascertained by a graduated series of exercises. By means of these exercises some are rendered fit to resume their pre-war employment, those who are not so fitted are recommended for suitable training in other employments, or if they require treatment for a definite cardiac disability, they are sent for 12 months to a treatment and training centre under the Ministry of Pensions. On the grounds of economy there is no resident medical officer; but in addition to the consulting cardiologist, who visits the hospital daily, the staff consists of an assistant medical officer, Dr. Branford Morgan. There are also a matron, a nursing sister, and a remedial instructor, who is responsible for the carrying out of the remedial exercises. These exercises are arranged in three grades:—

The first grade is designed with a view to restoring normal physiological movements, such as those of the limbs, trunk, and head, with especial attention to thoracic breathing. The D.A.H. case of some standing almost invariably breathes with the diaphragm and abdomen, the upper part of the chest becoming more and more flattened and inert, while the lower half of the abdomen becomes protuberant. So unused are these patients to deep thoracic breathing that a condition of apnœa and giddiness often results, after early efforts to regain it. This grade lasts 20 minutes.

The second grade is somewhat more strenuous than the first and involves actual effort, the deep breathing exercises being continued. The period of this exercise is 30 minutes.

The third grade is the most strenuous and includes hopping, lunging with arms and legs, quick march and doubling, and two games. The value of games is very high. Many patients, on account of the mental reaction associated with exercise in a definite form, show much reaction after ordinary drill. The same men can play vigorous games, such as ball-throwing, bumble puppy, and football, with little if any sign of distress.

The following three cases, observed at a recent visit to the clinic, may be taken as illustrative of the work done:—

1. A man, aged 30, who had served in France. Complains of shortness of breath and a little precordial pain. No history of rheumatic fever. He is found to have early mitral stenosis. There is a presystolic murmur at the apex, hardly perceptible when the patient is examined in the erect posture, but very distinct when lying on his left side. This case is able to do the hardest form of exercise with comparatively slight reaction.

2. A man, aged 28, with shortness of breath and a good deal of precordial pain. A diastolic murmur is heard, best at the third left costal cartilage, in full expiration. There is also a presystolic murmur at the apex. The case is an early one, and there is no suggestion of a Corrigan pulse. His exercise tolerance is very fair, exemplifying the usual rule that cases of early organic disease have less of the effort syndrome than those with functional disorders.

3. A case of paroxysmal tachycardia in a young man of 25 attending the clinic. The same condition had been observed in this case in 1917, and has not altered since. The cardiac rhythm is that of a regular series of irregular beats. There are two normal beats, followed by two to four very rapid beats and then two more normal beats, and so on. Except for some dyspnœa on exertion, and only a moderate exercise tolerance, the pensioner has very little complaint. Another very similar case, an in-patient, shows on the polygraph two to four normal beats, followed by six to eight quick beats of tachycardia, in a regular alternating sequence. This irregularity has been known to exist since early in 1918. This pensioner is able to do the highest grade of exercise, and has been at work as a stock-man since his discharge. He is not able to lift heavy weights or run for any distance.

The cardiovascular clinic is held once a week, on Thursday mornings. Cases are sent here from the Norfolk and neighbouring areas for diagnosis, assessment according to grade, and treatment.

BUDAPEST.

(FROM OUR OWN CORRESPONDENT.)

Responsibility of Doctors in Cases of Abortion.

AN illustration of professional difficulty arising in a case of abortion was lately afforded in the coroner's court at Debreczen, Hungary. A medical man was called to attend a woman who, a day or two afterwards, confessed she had taken a large dose of aloes and had procured abortion. He did not tell the husband of the state of affairs for 10 days, nor did he inform the parents to whose house the patient was then removed. Lastly, he did not inform the gynæcologist of the hospital, to which she was finally taken (and where she died) of the cause of her condition, although he stated that she was suffering from peritonitis. He excused himself to the coroner on the grounds that the matter was one of professional confidence, and that he did not regard the woman's condition as serious enough to warrant the taking of depositions. It is remarked in the medical journals that public opinion would doubtless commend the physician for his reticence in so far as the relatives were concerned, but that there was no reason why information, even of this delicate kind, should not have been given to the hospital doctor under whose care the patient subsequently came. Such an act could never be construed as a breach of confidence. Nevertheless, one medical writer held that it was preferable that medical practitioners should err on the side of discretion. But by remaining the sole depository of such a secret the practitioner may incur the risk of passing for an accomplice, besides making himself an accessory after the fact.

Small-pox in Albania.

An epidemic of small-pox has broken out in some parts of Albania; the medical authorities have communicated the facts to the Albanian, Jugo-Slavian, Roumanian, and Italian medical and lay papers, and measures are being taken to prevent the disease spreading. The municipalities have appointed special medical men to perform gratuitous vaccination, and the population is asked not to put any difficulties in their way. It is likely, however, that the vaccinators will be hampered in their work, especially in some quarters where the working classes look with suspicion upon every free measure of the sanitary authorities.

The Threat of Cholera from Russia.

The news of the outbreak of cholera in Russia is causing much anxiety here and in neighbouring states. It is feared that it will be impossible to prevent the scourge from spreading into Bessarabia. A day or two ago a suspicious case occurred at Kisenew; a man was taken suddenly ill and showed a number of symptoms characteristic of cholera, such as violent vomiting, diarrhœa, cyanosis, and collapse. The man died, and the news soon spread through the city that cholera had again appeared. I am informed, when attacked, lest a wrong impression should arise that arguments left unanswered are unanswerable.

I am, Sir, yours faithfully,

London, W., Dec. 10th, 1921. OTTO MAY.

ZINC IONISATION IN OTITIS MEDIA.

To the Editor of THE LANCET.

SIR,—In an annotation on Chronic Aural Suppuration in THE LANCET of Nov. 19th you remark, "It is generally agreed that the large majority of cases of suppurative otitis recover completely if treated from the onset." It has been my experience that a large proportion of these cases recovers completely when the surgeon carries out the treatment himself, or when the cases are taken into hospital and treated there as in-patients; that a smaller proportion recovers when the cases are seen as out-patients, say, once or twice a week, treatment being meantime carried out at home; and that, of course, a still smaller proportion recovers when untreated.

Now, the large majority of acute ear cases falls into the category of those seen occasionally by the surgeon and treated at home with, on the whole, not very satisfactory results. Any method which will substantially improve the results in this class is much to be desired, and such a method I believe that we possess in zinc ionisation. The apparatus required is simple, consisting of a galvanoset or some such source of current in which the ampèreage can be absolutely steadily increased and decreased, a short pencil of zinc as the positive electrode, a basin of water in which the patient's hand can be dipped as the negative electrode, and some weak sulphate of zinc to pour into the ear. Some otologists pass the zinc electrode into the ear through a vulcanite speculum with a special clip to prevent the electrode from slipping out. I find this, however, quite unnecessary; all one has to do is to wrap the zinc pencil in cotton-wool so as to prevent the metal from touching the skin.

The technique is simple: the ear must be cleansed and dried; the patient then lies down with the affected ear uppermost; the ear is filled with warm sulphate of zinc, 2 gr. to the oz.; the zinc electrode, wrapped in cotton-wool, is introduced into it; one hand is put into the basin of water with the negative electrode, and the current very slowly and steadily turned on, from zero up to one, two, or three M.A.'s, according to the tolerance of the patient, and still more slowly turned off after 10 to 15 minutes. The zinc sulphate lotion is then gently mopped out of the ear and a small pledget of cotton-wool put into the meatus.

In a recent case, with a perforation in the tympanic membrane large enough to admit of free access of the lotion to the inflamed area, one ionising is sometimes all that is required. For example:—

CASE 1.—Nurse E. had acute double otitis media following a severe cold, and was under treatment for five weeks. The right ear dried up but the left continued discharging pus. I ionised the left ear with zinc 3 M.A.'s for 10 minutes. Two days later the ear was quite comfortable, almost dry, quite dry after another two days, and since then has given no further trouble.

CASE 2.—Miss T. had acute earache lasting a few hours, relieved by bursting of drum with blood-stained serous discharge. Two days later I began dressing with ribbon gauze moistened with carbol-glycerine: five days later muco-purulent discharge continued. I then ionised the ear with zinc 1 M.A. five minutes. Next day the ear was dry, quite comfortable, and has given no further trouble.

In these cases the perforation was rather large, the discharge was not very profuse, and I had no reason to suppose that there was any involvement of bone.

On the other hand, ionisation cannot be expected to cure cases in which there is a very small perforation, or in which there is a very profuse, persistent discharge, indicating inflammation of the antrum and possibly mastoid cells, e.g.:—

CASE 3.—Mr. B., during convalescence from an attack of pneumonia, developed acute otitis media sinistra. I found a very profuse discharge, a rather small perforation in the membrane, slight mastoid tenderness. Operation was refused. Other treatments had little effect. I ionised the ear three times, but with no result whatever.

CASE 4.—Mr. J., during a cold had some pain in the left ear, which was relieved when a blood-stained serous discharge appeared. In his case the discharge was never profuse, but the perforation was very small; ionisation had no appreciable effect.

When suppurative otitis has become chronic, or when the bone cavity left by a mastoid operation has either refused to heal, or after healing has broken down again, ionisation will often effect a cure.

CASE 5.—Miss B. had a radical mastoid operation performed about 12 years ago. This healed and remained well till she was sent to France on war work. Then the mastoid broke down, and, in spite of treatment very thoroughly and carefully carried on, continued discharging for four years. She then came to me for ionisation. The cavity was healed after six sittings, and has remained dry and given no trouble since.

CASE 6.—Miss L., with a history similar to the last, required 12 sittings before the mastoid was finally dry. When I began treating her ear I ionised twice a week, which is probably too frequently, once a week being enough.

Some chronic cases do not yield to this treatment. Small perforations, the presence of granulation tissue, too profuse discharge are obvious difficulties that need hardly be mentioned; but a few cases that I thought ought to do well have not responded; I do not know why. I cannot claim to speak from a large experience, but my results in suitable cases have been so good that I feel justified in urging more otologists to adopt the treatment. I am, Sir, yours faithfully,

Brighton, Dec. 8th, 1921. ARTHUR J. HUTCHISON.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Capt. W. G. McKenzie, from R.A.M.C., General List, to be Capt.

ROYAL AIR FORCE.

Flight Lt. R. J. Monahan relinquishes his temporary commission on ceasing to be employed.

THE CALCUTTA CENSUS.—The municipal authorities have from the first doubted the accuracy of the results of the census taken in Calcutta. The increased demand for water, the extraordinary scarcity of housing accommodation and other broad facts all pointed to a large increase of population, and hence, when it was found that growing districts were reported to have lost in population, it seemed clear that someone had blundered. The chairman of the corporation, at the instance of the general committee, asked the census authorities for help in checking the census results in certain wards, and the proposed check has just been accomplished. Its outcome is to show that, as was suspected, the official enumeration was singularly defective. Immediately the census was over, dozens of persons reported that they had not been counted. It is now found that on the figures tested the omissions were between 12 and 15 per cent. Such a departure from the facts must falsify death-rates, birth-rates, and all municipal statistics. It seems inevitable that another census must be taken next March if municipal returns are to be useful as records. The low general death-rate of 31 recorded for the week ending Nov. 12th, the latest of which we have any record, is far below the five-year mean of 39·5, but the apparent diminution may be due in part to just such censal inaccuracy as has been shown.

prevalent in low and damp localities, where it is endemic and where it occasionally breaks out into local epidemics. It has also been recorded that, proportionally to the population, diphtheria is more frequent in villages than in towns. In districts where diphtheria is endemic the forms of the disease are always mild even in the occurrence of a local epidemic; the contrary has been observed in regions where diphtheria occurs only occasionally. Between 1911 and 1920 cases of tuberculosis brought to the notice of the medical officers of health of the county numbered 3069. According to these figures the proportion of cases is 8 per 1000 inhabitants. It appears though that the number of cases of tuberculosis is greater than one would expect from the notification figures, since the *annual number of* deaths due to the disease is approximately 900. According to statistics, tuberculosis is just as prevalent in the country as it is in industrial centres; in 11 towns of 5000 inhabitants and over for which the total population amounts to 92,610 inhabitants, 825 cases have been recorded—that is, 8·90 per 1000; in 49 boroughs of 1000 to 5000 inhabitants and for which the total population is 85,841 inhabitants, the number of cases of tuberculosis is stated to be 766—that is, 8·09 per 1000; in 402 villages of less than 1000 inhabitants 1372 cases of tuberculosis have been detected, the proportion being calculated as 8·54 per 1000. Dealing with these statistics Dr. Paquet emphasised the fact that they were absolutely opposed to the general belief that tuberculosis is more frequent in towns than it is in the country. He thinks that the findings are sufficiently explained by the spread of alcoholism to the rural districts; by work done at home under most unhealthy conditions, such as the making of brushes, and the assembling of parts of boots; and by the return of contaminated workmen to their country homes, where they spread the disease.

Prizes at the Académie des Sciences,

The Members of the Académie des Sciences have awarded various prizes as follows: Prix Bréant (Fr. 5000) to MM. E. Dujardin-Beaumetz and E. Joltrain, bacteriologists to the Pasteur Institute, for their book "History of an Epidemic of Plague in Paris." Fonds Charles Bouchard (Fr. 5000), presented to Mr. M. Ménard, radiologist to the Cochin Hospital (Paris), for his works on radiography. Prix Montyon (Medicine and Surgery), comprising various prizes—three of Fr. 2500, three of Fr. 1500, and one of Fr. 1000, respectively—to Mr. E. Roubaud, pathologist to the Pasteur Institute, for his works on malaria in France; to MM. A. Sieur, médecin inspecteur général de l'Armée, and R. Mercier, professor at the Medical School of Tours, for a series of records, "Le Service de Santé du Groupe d'Armée Fayolle en 1911"; to Mr. E. Bourdelle, professor of anatomy in the Veterinary College (Alfort), for a text-book on Regional Anatomy of Domestic Animals; to Mr. E. Antoine, interne des Hôpitaux de Paris, *for his* work on Severe Forms of Proctitis and Colitis; to Mr. M. Rubinstein for a text-book on Serology and Sero-diagnosis; to Mr. A. Vernes for his work "Atlas de Syphilimétrie"[1]: to Miss A. Forget, directrice de l'Œuvre, for her book on Re-education of Speech. The Prix Montyon (Physiology) (Fr. 700) was awarded to Mr. H. Piéron, director of the laboratory of psychophysiology of the Sorbonne, for his study of reflexes and muscular tone; Prix Barbier (Fr. 2000) to Mr. E. Saquépée, professor at the Val-de-Grâce Hospital, for his work on gas gangrene; Prix Lallemand (Fr. 1800), granted to MM. G. Guillain, professeur agrégé of the Faculté de Médecine de Paris, and A. Barré, professor of the Faculté de Strasbourg, for their work "Travaux Neurologiques de Guerre"; Prix Argut (Fr. 1200) to Mr. F. de Courmelles, for his works on X rays and radium in gynæcology; Prix Godard (Fr. 1000) to MM. A. Chalier, chief of the surgical clinic of the Faculté de Médecine de Lyon, and X. Delore, surgeon of the hospitals at Lyon, for their work on tuberculosis of the genital organs; Prix Philipeaux (Fr. 900) to Mr. E. Grynfeltt, professeur agrégé of the Faculté de Médecine de Montpellier, for his work on the histology and the embryology of the eye of the vertebrates; Prix du Baron Larrey (Fr. 700) to Mr. G. Ferry, assistant at the surgical clinic of the University of Strasbourg, for his works entitled "Aviators' Disease" and "Fitness for Air Service."

Dec. 8th.

MEDICAL AND PHARMACY BILL FOR SOUTH AFRICA.

Among the important measures to be introduced by the South African Government when the Union Parliament meets on Jan. 20th is a Bill "to consolidate and amend the laws in force in the Union relating to medical practitioners, dentists, pharmacists, midwives, trained nurses, and other classes of persons; the keeping and sale of poisons; the importation, sale, and use of habit-forming drugs; and as to other matters connected therewith or relating thereto." The Bill is the outcome, and practically a re-draft, of a similar measure considered originally by a Select Committee in 1917; its provisions are based upon the information then elicited, together with reports since obtained from the various medical councils and pharmacy boards. The chief provisions of the Bill are:—

1. Abolition of the existing four provincial medical councils and four pharmacy boards, and the constitution of a new South African Medical Council and a new South African Pharmacy Board, with extended powers.
2. Registration of medical and dental students studying at any South African university at which a medical and dental faculty is or may become established.
3. Alteration in registration fees.
4. Replacement of the term "chemist and druggist" by "pharmacist."
5. Provision against medical practitioners keeping an open chemist's shop.
6. Provision for the carrying on of a pharmacy by a limited liability company or other plurality of persons.
7. Certain protections for native medicine men.
8. Additions to the poisons laws, including more stringent regulations and limitation of storekeepers' sales.
9. Institution of a poison section.
10. Chapter dealing with opium and habit-forming drugs.

The new Medical Council is to be appointed for five years, and is to consist of 14 medical practitioners and four dentists, some of whom are to be nominated by the Government and the rest by the practitioners. The new Pharmacy Board is also to hold office for five years, and is to comprise eight pharmacists and one medical practitioner, an official of the Public Health Department. Certificated midwives and trained nurses, &c., will be granted permission to elect a registered person to the Council. Provision is also made for nominees to the Council and Board from any university which has established a faculty of medicine, and from any school of pharmacy approved by the Board. The names of all persons at present registered in any of the four provinces will be embodied in the new Register, with the exception of persons whose addresses are outside the Union or are recorded as unknown. The new Register will comprise medical practitioners, dentists, pharmacists, certificated midwives, trained nurses, medical and dental students. The Register will abolish the existing anomaly that, although the Union has been in existence for over 11 years, it is not permissible to-day for a person registered in one province only to practise in any of the other three provinces. No foreign diplomas are to be recognised unless reciprocity exists between the Union and the country issuing such diploma. The new registration fees will be: medical practitioners, £25; dentists, £25; pharmacists, £12 10*s.*; midwives and trained nurses, £2 10*s.*; additional degrees or diplomas, £1.

---

[1] See Review, The Lancet, July 23rd, p. 183.

Literary Intelligence.—Mr. Humphrey Milford announces the forthcoming publication of "The Records of the Augustinian Priory of St. Bartholomew, West Smithfield, and of the Church and Parish of St. Bartholomew the Great in the City of London," by E. A. Webb, F.S.A.

Metropolitan Hospital Sunday Fund.—The annual meeting of the constituents of this fund will be held at the Mansion House on Monday, Dec. 19th, at 3 P.M. The business of the meeting is to receive the report of the Council for the year 1921, to elect the Council for the year 1922, and to determine the date of next Hospital Sunday.

Cancer Hospital Dinner.—The Medical Committee of the Cancer Hospital entertained a number of guests to dinner at the Hotel Cecil on Dec. 8th. In proposing the health of the hospital, Sir Charles Ryall, the chairman, alluded to the finances of the hospital; in common with others they had been adversely affected by the war, but the foundations of the charity having been laid on a sound basis they were still able to carry on under the voluntary system. The clinical material at the Cancer Hospital, drawn from the immense population of London and the home counties, had recently attracted medical students from two of the London medical schools, and medical men, as house surgeons, from the Antipodes. Some of their best residents had come from New Zealand, and the hospital would always welcome the colonial who came to London, after graduating, to complete his medical education. The health of the guests was proposed by Sir Thomas Horder. Sir James Allen, High Commissioner for New Zealand, in replying, thanked the hospital for their care of the men from his colony, and alluded to the interest felt in New Zealand in the problems of cancer and tuberculosis. Sir Kingsley Wood, Parliamentary Secretary to the Ministry of Health, and Sir Percival Horton-Smith-Hartley, chairman of the medical committee of the Brompton Hospital, also spoke. Mr. Cecil Rowntree proposed the health of the chairman, expressing the warm admiration felt for him by his colleagues as a surgeon, counsellor, and friend.

Tuberculosis in Dublin.—Dr. P. J. Murray, the chief tuberculosis officer for Dublin, has recently issued his report for the year 1920. The most noteworthy feature in his report is the record of the regular and steady diminution in the mortality from tuberculosis in the past six years. In 1915 there were in the city 1513 deaths due to the disease, of which number 1193 were due to pulmonary tuberculosis. The numbers decreased every year until in 1920 they have fallen to 820 and 615 respectively. This may be regarded as something of an achievement in view of the fact that the present scheme for dealing with tuberculosis only came into being in 1913. The scheme at present embraces (1) a dispensary, (2) a sanatorium, and (3) a hospital for chronic or advanced cases. There are also arrangements for treating the various forms of surgical tuberculosis in the city hospitals, and subsequently, if necessary, in convalescent homes. Dr. Murray advises the provision of an institution for the treatment of children suffering from pulmonary tuberculosis. He is of opinion that the topographical and climatic conditions of Dublin have little influence on the incidence of the disease, which is much more affected by the conditions under which the poorer inhabitants are obliged to live. He has found domiciliary treatment less useful than institutional because of the deplorable housing conditions of so many of the working people, conditions which render any attempt at isolation nugatory. He notes that more than half of the new cases examined in 1920 were in families living in not more than one room to a family.

Royal Institution.—The following are the lecture arrangements at the Royal Institution before Easter: Prof. J. A. Fleming, six lectures adapted to a juvenile auditory on Electric Waves and Wireless Telephony, beginning on Thursday, Dec. 29th, with a lecture on Surface Waves on Liquids, and followed by lectures on Waves in Air, the Telephone, Electric Oscillations, Electric Waves, and Wireless Telephony. On Tuesday afternoons, commencing on Jan. 17th, 1922, there will be two lectures on Physiology as Applied to Agriculture, by Dr. F. H. A. Marshall; three by Prof. H. H. Turner on Variable Stars; five by Sir Arthur Keith on Anthropological Problems of the British Empire—Series I., Racial Problems in Asia and Australasia; and two by Dr. J. W. Evans on Earth Movements. On Thursday afternoons Mr. Seton Gordon will give two lectures on Mountain Birds of Scotland and Sea-Birds and Seals; Sir Napier Shaw two on Droughts and Floods; Prof. A. G. Perkin two on Dyeing, Ancient and Modern; Prof. H. Maxwell Lefroy two on the Menace of the Insect Pest: The Balance of Life in Relation to Insect Pest Control; Dr. P. Chalmers Mitchell two on the Cinema as a Zoological Method; and Prof. A. M. Hind two on Landscape Etchers: New and Old. On Saturdays there will be two lectures by Dr. L. de Selincourt on Humorists of the Seventeenth Century—I. Sir Thomas Browne, II. Thomas Fuller; two by Prof. E. A. Gardner on Masterpieces of Greek Sculpture; and six by Sir Ernest Rutherford on Radioactivity. The first Friday evening discourse will be given on Jan. 20th by Sir James Dewar on Soap Films and Molecular Forces. Succeeding discourses will probably be given by Viscount Burnham, Sir Francis Younghusband, Prof. W. D. Halliburton, Dr. R. S. Watson, Prof. J. Joly, Dr. C. M. Wenyon, Prof. T. R. Merton, Dr. A. P. Laurie, Prof. F. G. Donnan, Mr. A. B. Walkley, Sir Ernest Rutherford, and other gentlemen.

The late Dr. Matthew Owen Coleman.—The death is recorded of Dr. M. O. Coleman, who had been medical officer of health for Surbiton for 45 years, at the age of 76. Dr. Coleman qualified M.R.C.S. Eng. in 1867 from Guy's Hospital, taking his M.B. Aberdeen in 1868 and M.D. Aberdeen in 1871. He became interested in public health early in his career, and in addition to a large private practice undertook the duties of an M.O.H., taking his D.P.H. in 1893. Dr. Coleman was very popular in the district he had served so long, and his death will bring grief to many colleagues and old friends.

Welsh National School of Medicine.—This school is now making a public appeal for a capital sum of £100,000 for the purposes of endowment and further equipment. This is necessary in order to place the institution in a position to quality for certain Treasury grants which are subject to the conditions being complied with before August, 1922. The promised grant of £5000 per annum will be forthcoming only in the event of the school raising by public subscription an equivalent annual income, or, in the alternative, a capital sum that will yield this revenue. The time is short and the matter is of great urgency. The Prime Minister has signed an appeal in which he sets forth the aims of the school, pointing out that to enable the school to give a complete training in all branches of medicine and surgery on this system will require a yearly expenditure of at least £25,000, to meet which the grants available from public sources and fees will be quite inadequate. A new physiological block and a department of public health are being built, and chairs of preventive medicine and tuberculosis have been founded. Further expenditure on equipment in the shape of laboratories and apparatus is necessary, and an endowment fund is required to provide the full complement of professors, lecturers, and trained staff which the hospital unit system requires. Mr. Lloyd George adds that the King Edward VII. Hospital at Cardiff has placed all its beds at the disposal of the school for tuition purposes, and that nothing except money is now needed to make this one of the foremost schools of medicine in the country. Donations should be sent to the organising secretary, Mr. Gwilym Hughes, at the National School of Medicine, Newport-road, Cardiff.

The late Dr. Thomas MacQueen.—Dr. Thomas MacQueen, who died suddenly at Eastbourne on Dec. 1st, had been in poor health. He underwent a severe operation about ten years ago, but he was able to continue in practice until the end of his life. Dr. MacQueen took the M.B. degree at the University of Edinburgh in 1873 and became M.S. the same year; he held house appointments at the Queen's Hospital, Birmingham, and at the Royal Hospital for Diseases of Children in Edinburgh. During the Russo-Turkish war of 1877–8 he acted as surgeon to the Stafford House Society, and later settled at Eastbourne. Highly respected by everyone with whom he came in contact, he soon had an extensive practice. For many years he was on the medical staff of the Princess Alice Hospital, and as a prominent member of the Hartington Lodge of Freemasons he was Master in 1886 and received Provincial honours in 1893. He was 70 years of age, and leaves a widow, son (Dr. R. C. MacQueen), and daughter to mourn their loss.

Dr. W. Muir Smith, of Eastbourne, writes of Dr. MacQueen: "By his death the local medical profession in Eastbourne has lost one of its oldest and most respected members, and the town one of its most esteemed citizens. In 1879 he settled in Eastbourne, joining the late Dr. G. Mundie and Dr. H. Habgood in an extensive general practice, which was only dissolved in 1917 when Dr. Habgood retired from practice. He took a keen interest in the municipal and social affairs of the town, serving for three years on the town council, when he rendered excellent service on the sanitary committee. After a serious operation in 1910 Dr. MacQueen never recovered his former vigour although he continued, with the assistance of his son, who in 1910 joined him in partnership, to pursue some of his professional activities. His death will be poignantly lamented by many in the humbler walks of life, who had come to regard his assiduous care and ready sympathy with feelings akin to reverence. He leaves nothing but friends behind."

has described. When the time has come for the deliberations of professors and specialists to be leavened by the common-sense views of the general practitioner, the recently qualified, and even the unqualified student, the chances of reforms being both mooted and carried will be increased.

Let us take the attitude of the general practitioner who, after many years of practice, indulges in a retrospect of his training and tries to form an estimate of its value as judged by its influence on his career. He may perhaps find that in his practice about 50 per cent. of his patients suffered only from functional disturbances, that his success or failure in these cases depended on the degree of psychological skill he was blessed with, and that psychology was a subject totally ignored by his teachers throughout his career as a student. In many other matters his retrospect may leave him with a no more respectful opinion of professors than that with which Bismarck was credited. It is a thousand pities that the general practitioner, who knows better than any other class exactly where the shoe pinches, should be so voiceless in the task of bettering matters for the coming generations of medical students. It is well to remember that only a small fraction, say 5 per cent., of medical men become teachers and specialists. Yet this small minority has hitherto enjoyed a monopoly in the control of medical education, and has imposed its will on an unconsulted majority. This minority of nimble-witted examinees knows little of the struggles of the less gifted majority, who flounder through their examinations with much toil and many a reverse. Having passed their examinations with ease and distinction, it is almost inevitable that the prize-snatching minority should feel satisfied that all is well with the medical curriculum, and that they should be tempted to add to its complexity rather than to simplify it. Again, anyone who breathes the air of the students' quarter in hospitals knows how discontent seethes with regard to certain subjects in the medical curriculum. Why should not there be an outlet for this discontent, some of which may be justified? The question is surely pertinent.

The older generations do, no doubt, enjoy a judgment and perspective denied to callow youth; but the student possesses first-hand knowledge and is often more vitally interested in the matter than elderly teachers. Not only does the student often have a shrewd conception of the comparative value of the different subjects he is expected to master, but he also knows much better than his seniors which of his teachers are efficient and which are more or less incompetent. Yet he is allowed little or no choice, and many a misspent hour is the outcome of regulations enforcing attendance at the lectures of a dull and droning "teacher." Some years ago, at a Continental university, a professor of surgery became so notoriously incompetent as a teacher and unfair as an examiner that a deputation of medical students waited on the university authorities, insisting on his early retirement. This took place shortly afterwards. But for every such instance of vindication of the rights of the student, there must be dozens in which the forces of reaction and inertia have prevailed. It is so easy for these forces to invoke the privileges of age and experience.

Thoughts like these were, perhaps, passing through the mind of Prof. J. Madison Taylor when he sat down to compose his thesis[1] on "A New Conception of Medical Education and Medical Practice." With personal experience of general practice, he has brought to his present position as Professor of Physical Therapeutics and Dietetics in Philadelphia an outlook not exclusively academic. The principle of his scheme is the sorting out of medical students for different spheres of usefulness early in their career. He regards as wasteful the old system of passing every student through the same tests, irrespective of his individual abilities, and he visualises a future with three different grades of medical practitioner. The first and lowest grade he quaintly describes as the "drug store type." This "type" is meant to cope with walking cases, to deal practically with minor surgical and medical emergencies, to have experience in dispensary work, and to be qualified to practise after two years of "part-time studies." The second grade or "panel" type is to be qualified for more serious emergencies, to visit homes, to care for the average patient, and when "the problems exceed his training," to call in consultants. The period of training required for this grade of practitioner to become competent and "up to all ordinary practice," is to be three years. For the third and highest grade, a four years' course is suggested, part of the fourth year being devoted to such specialities as obstetrics and major operations. Although the humble-minded student, conscious of his inability to become a shining light in the medical profession, would be able to complete his studies in two years and then begin earning his living, opportunities to rise from one grade to the other would not be lacking, and he might ultimately reach the third or highest grade.

Another suggestion put forward by Prof. Madison Taylor is that there should be preliminary tests of the student's intelligence, gumption, or common-sense. "For the higher class medical adviser greater emphasis should be laid on the more abstract processes of intellectation." This paper conveys a bizarre impression. The conception of a cross between an orderly and a mediæval barber-surgeon—the product of two years' training—is somewhat startling; and, judged by European standards, the notion that a consultant surgeon or physician can be evolved in four years seems a whimsical fantasy. But these considerations should not blind us to the essence of Prof. Madison Taylor's scheme, and if we make due allowances for the very different conditions of medical practice obtaining in the U.S.A., and remember that what may seem startling and unconventional to us may be the acme of common-sense beyond the Atlantic, we may come to the conclusion that the principle for which Prof. Madison Taylor is fighting is sound. Until we are satisfied that our educational system is made sufficiently flexible to meet the needs and qualifications of the individual, and till it is modelled on the requirements of the student in his post-graduate career, it is our obvious duty to provide ventilation for grievances and to leave the door open to reforms. I am, Sir, yours faithfully,

Dec. 10th, 1921. C. L.

SELF-DISINFECTION.

To the Editor of The Lancet.

Sir.—May I be allowed a word of comment on the annotation in your issue of Dec. 10th dealing with the articles contributed by Sir Archdall Reid and myself to the *International Journal of Public Health ?* On receiving the invitation to write the article in question, I suggested to the editor that the controversy on "self-disinfection" was essentially a "domestic" one, and that it was undesirable to parade it in an international journal circulating in other countries in which this question is rightly regarded as of minor importance in the campaign against venereal disease. I added that, if the subject was to be broached at all, it would be better to have a single article, written by someone not specially identified with either side, and free from polemics. I received the reply, however, that Sir Archdall Reid had already accepted the invitation to contribute a paper, and that the *Journal* was thereby committed to its publication. Rather than to allow judgment by default, I agreed, though against my inclination, to write the short article to which you have alluded.

The National Council fully realises the harm done to the anti-venereal campaign by public controversy on "self-disinfection," and has always refrained from initiating such controversy either in the medical or the lay press. The most that can be urged against it is that occasionally it has ventured to defend itself

---

Notes, Short Comments, and Answers to Correspondents.

THE DOCTRINE OF INFECTION THROUGH THE AGES.

THE last Chadwick lecture of the present session was delivered at the Barnes Hall of the Royal Society of Medicine on Dec. 8th, Sir James Crichton Browne presiding, by Dr. Charles Singer, who discussed the history of the doctrine of infection.

In Prehistoric and Classical Times.

In modern times, Dr. Singer said, a mother suspecting her child to be suffering from measles would promptly call in a physician, who might confirm her suspicions, informing her at the same time that the child had contracted the disease from a schoolfellow whom the physician had been attending for some days. Two thousand years ago the family friend and physician would have assured the Roman mother that the atmosphere was in a pestilential state, that in time this pestilential character of the atmosphere would pass away and that in a few days perhaps the patient would recover. In a lake village of, say, 10,000 years ago, modern views might have prevailed; not only would an infection be considered to be conveyed from one person to another, but other things, such as a broken arm, would be attributed to the same cause, the idea of infection having a much wider meaning. Good luck was infectious, virtue and vice every form of happiness and unhappiness.

Why the ancients of classical times did not believe in infection in the wide sense, while the primitive people believed everything to be infectious, had its root-cause, Dr. Singer said, in each case in the group of philosophical ideas formed regarding the nature of the world in which they lived. By a process of sympathetic magic early man considered that moral qualities and powers passed from person to person in the same way as physical attributes were conveyed from object to object. Early sanitary legislation was based on this doctrine of sympathy. Classical writers, on the other hand, held a rationalistic attitude towards phenomena in general and disease in particular. The element of infection was thrown into the background and emphasis was laid rather on the atmospheric element or miasma. Galen regarded most epidemic diseases as due to changes in the only universally acting medium, as he considered, the air; to him, few diseases were conveyed from person to person, among these few, be it noted, was phthisis. Infection from person to person remained mainly the layman's view, beginning with Thucydides and handed on through the dark ages by St. Isidore, who died in 636 A.D. During the scholastic period which in medicine extended from the twelfth to the middle of the sixteenth century, the prevalent medical teaching was derived from works translated from the Arabic, although few, if any, of the writers were Arabs, the doctrines propounded being derived from and essentially similar to those of the classical writers. Arabian medical authors, however, laid more emphasis on the passage of disease from person to person than did the Greek physicians. After this came the fatalistic reaction when the sale of medical books was forbidden, and many of them were destroyed, Galen's works fortunately escaping destruction.

In the Middle Ages.

Western Europe, Dr. Singer continued, between the Black Death of 1347–49 and the middle of the sixteenth century was swept by an appalling series of epidemic outbreaks of plague, typhus, influenza, small-pox, syphilis, and sweating sickness, which gave rise to a considerable literature, at first mainly of Arabian origin. From 1490 to 1550 this literature came under the influence of rationalistic Renaissance philosophy, from which the modern doctrine of infection took its rise. Hieronymo Fracastor might be called the father of epidemiology; he invented the word syphilis and was one of the earliest to describe that disease. His great work "De Contagionibus" was published at Venice in 1543. He regarded infection as the result of small seeds or semina, so minute as to escape the sense of vision, but having the power of multiplication. These seeds were specific for each infectious disease, they could arise de novo as the result of atmospheric disturbance or of corruptions and especially of certain astral influences. It was useless, said the lecturer, to discuss whether Fracastor considered the semina living or not, for he made no distinction between living and non-living matter, belonging as he did to a philosophical school which held all material substance to be pervaded by some sort of living principle. He made, however, a close and pregnant comparison between infection, putrefaction, and fermentation. Fracastor's views were widely accepted in the sixteenth and seventeenth centuries being amplified by such writers as Paracelsus, Jerome Carden, and Gabriel Fallopius, but remaining for the most part the current explanation of the phenomena of infectious and epidemic disease.

CALENDARS AND DIARIES FOR 1922.

THE Anglo-French Drug Co., Ltd., of 238a, Gray's Inn-road, London, W.C., have issued their diary for 1922 made in the handy form of a block calendar with a page 6 by 4½ inches for each day, containing ample space for memoranda. The diary is intended to lie on the desk and is provided with a cover containing a window permitting the date always to remain in sight. It can be obtained free on application.

EPILEPTIC FITS AND ATMOSPHERIC POTENTIAL.

IN a paper presented to the Balneological Section of the Royal Society of Medicine on Dec. 8th Dr. A. G. S. Mahomed compared the published records of atmospheric electrical potential from Kew Observatory with the number of epileptic fits recorded day by day among the inmates of Epsom Colony and Caterham Mental Hospital. The periods chosen for comparison were the first half-years of 1912 and 1919. Dr. Mahomed found potential and fits started high in January, were about at the average level in April, and sank below it in the succeeding months. June did not agree with the rule. The observations are suggestive, although Dr. Mahomed has not worked out mathematically the actual correlation value.

HOSPITALS AND DISPENSARIES IN BENGAL.

IT is well known, as remarked by Major-General W. H. B. Robinson, C.B., K.H.S., I.M.S., Surgeon-General with the Government of Bengal, in his report on Hospitals and Dispensaries for the years 1917–18–19 (Calcutta, 1920) that there is need for more qualified practitioners "of the Licentiate or School Standard" in that province; and in order to meet this demand the sanctioned strength of students in the Campbell and Dacca Medical Schools has been increased to 500 and 400 respectively. Moreover, a new medical school, especially for western Bengal, with accommodation for 200 students, is in course of construction at Burdwan, and is expected to be opened in the present year; also the Carmichael Medical College at Belgachia, together with the Albert Victor Hospital attached to it, are both being enlarged and improved. The School of Tropical Medicine at Calcutta was completed four years ago, but has not yet been opened; the buildings are now being extended to include laboratories, &c., for the teaching of hygiene. The total hospital accommodation in Calcutta at present amounts to 2385 beds in 16 hospitals, as compared with 2323 beds in 14 hospitals at the end of 1916; but all these institutions are more or less overcrowded, a considerable number of beds having to be given up to incurables and permanent cripples. There is urgent need for a suitable refuge for these cases, as well as for a convalescent home to relieve the pressure on the very costly hospital beds. The average number of patients treated per annum in these Calcutta hospitals was 446,209, compared with a similar average of 397,074 in the preceding triennium, the increase being due partly to prevalence of influenza and small-pox; out of this average annual total the in-patients numbered 32,325, with a death-rate of 14·49 per cent. At the Campbell Hospital as many as 11,873 patients were treated, a very large increase on the admissions for 1918 (7250), and 1917 (5575). Great credit is due to the superintendent, Lieut.-Colonel A. Leventon, for his success in meeting the enormous demands on the accommodation at his disposal. This hospital is now "highly popular among the middle and humbler classes," and a much needed enlargement has been taken in hand.

Among the chief diseases prevalent during the three years reported on were influenza in 1918 and 1919, cholera in each year, kala-azar, and tubercle of the lung. Admissions for malaria, pulmonary tubercle, and venereal diseases were less numerous in Calcutta in 1917 and 1918 than in 1916. The death-rates in cholera among in-patients were 22·6, 24·5, and 28·1 per cent. for the three years, 1917–18–19, respectively, "a very high testimonial to the Rogers treatment by intravenous saline, especially when one considers the very critical condition of the cases on admission." In the districts there was an increase in malaria (more than one-third of the total patients attending dispensaries being under treatment for this disease). Injection of quinine salts gave satisfactory results. Surgeon-General Robinson, in his concluding remarks, gives a well-deserved tribute to the excellent work of the medical officers of the Indian Medical Service and of the military and civil assistant surgeons, and draws attention to the inadequacy of pay in the case of the two latter. This matter has been long under consideration, and it is hoped that improvements will be effected without further delay.

Medical News.

Royal College of Surgeons of England.—An ordinary Council meeting was held on Dec. 8th, Sir Anthony Bowlby, President, being in the chair.—A report was read from the Court of Examiners respecting candidates found qualified for the diploma of Fellow. Diplomas of Fellowship were granted to 26 candidates.—A report was read from the Board of Examiners in Dental Surgery respecting candidates found qualified for the Licence in Dental Surgery. Licences in Dental Surgery were granted to 63 candidates.—Sir Anthony Bowlby and Sir John Bland-Sutton were re-elected representatives of the College on the Conjoint Board of Scientific Societies for the year 1922.—The President reported that he attended in the lecture theatre of the College on Thursday, Nov. 17th last, the day appointed for the annual meeting of Fellows and Members, and that, as the required quorum of 30 was not present at the expiration of 15 minutes from 3 P.M., the hour for which the meeting had been summoned, he had announced that the meeting could not be held. The President also referred to certain irregular proceedings which appear to have taken place on this occasion after his withdrawal from the theatre, and suggested that it might be a matter for the future consideration of the Council as to whether, or not, any steps should be taken in view of these irregular proceedings. It was thereupon referred to a committee to consider and report to the Council regarding the irregular proceedings to which the President had called attention.—A letter was read from Mr. H. Waring reporting the proceedings of the General Medical Council at their recent session, and the Council thanked Mr. Waring for his services as the representative of the College on the General Medical Council.

Of the 113 candidates who presented themselves at the recent examination for the Fellowship 26 were approved and 87 were rejected. The following are the names and medical schools of the successful candidates:—

Lyon H. Appleby, London Hosp.; Wilfrid H. Bleaden, Oxford and St. George's; Marian N. Bostock, Royal Free and St. George's; George A. Brookes, Sydney and London; George G. Bruce, Aberdeen and St. Bart.'s; Noel St. John G. Dudley Buxton, Univ. Coll.; Hugh W. B. Cairns, Adelaide and London; Robert C. Davenport, St. Bart.'s; Griffith I. Evans, Oxford and St. George's; Charles M. Finny, Dublin; Lionel B. Goldschmidt, King's Coll.; Ronald B. Green, Univ. Coll.; Alfred H. Heslop, Durham and St. Thomas's; Eric I. Lloyd, Cambridge and St. Bart.'s; Arthur J. McNair, Cambridge and Guy's; Victor E. Negus, King's Coll. and St. Mary's; Donald C. Norris, Paris and London; Eleanor J. Partridge, Royal Free; Robert Y. Paton, Cambridge and St. Mary's; Hugh Reid, Liverpool and London; Gilbert I. Strachan, Glasgow and London; Donald McKay Sutherland, Manchester; Maurice L. Treston, London; Austin D. Wall, St. Bart.'s; Alfred B. K. Watkins, London; and Leslie H. W. Williams, Cardiff and Univ. Coll.

Licences in Dental Surgery were conferred upon the following:—

Dorothy M. Allen, Royal Dental; H. C. Ardouin, Univ. Coll.; H. J. Barrand, T. E. Brevetor, J. H. Broadhead, and I. Broude, Guy's; J. B. Chenoy, Royal Dental; H. C. Churchill, P. N. C. Conway-Jones, F. W. Crook, J. L. de Kock, J. I. do Villiers, and D. I. du Buisson, Guy's; D. M. Edmonds, Royal Dental; F. J. Farmer, W. M. K. Gray, and A. W. Greenwood, Guy's; O. C. M. Haines, Royal Dental; F. J. Hagen, Univ. Coll.; A. W. Hall, Royal Dental; C. Hardwicke and A. Havenga, Guy's; F. Hiam, Royal Dental; F. R. Hogbin, Guy's; E. E. M. Horton, London; W. H. Hume, Royal Dental; Petronel Iago, Univ. Coll.; H. Jackson, Royal Dental; G. K. Jennings, B. J. M. Keyter, O. F. A. Krause, J. A. Krige, J. Lanchester, A. S. Landsler, S. Levinson, and H. J. Luck, Guy's; E. I. Morgan, London; W. J. Olivier, E. C. Packham, O. F. R. Painter, and H. H. Pickett, Guy's; C. L. T. Pocock, Royal Dental; E. M. Power, G. E. Price, and G. P. Pritchard, Guy's; L. Rabinowitz, London; S. H. Rands, H. J. Raubenheimer, and J. H. Reid, Guy's; B. A. Rilot, Royal Dental; P. M. Rohan, Univ. Coll.; F. H. Rowat, Royal Dental; A. F. Searle, London; W. E. Silver and J. S. Smith, Guy's; R. R. Steele, Royal Dental; F. W. van der Hoven, H. van Zyl, and H. P. Ward, Guy's; A. I. Williams, Royal Dental; and G. S. W. Willis, T. E. Withers, and F. Woodford, Guy's.

Royal Faculty of Physicians and Surgeons of Glasgow.—At the monthly meeting of the Faculty held on Dec. 5th the following were admitted, after examination, as Fellows of Faculty:—

Donald McIntyre, M.B., Ch.B., F.R.C.S. Edin.; Osborne Henry Mavor, M.B., Ch.B.; John Ivison Russell, M.B., Ch.B.; David Smith, M.B., Ch.B., M.D.; David Steven, M.D.; William Richard Wiseman, M.A., B.Sc., M.B., Ch.B.

Royal College of Physicians of Edinburgh.—At the annual meeting of the College held on Dec. 1st Sir Robert Philip was elected President for the ensuing year. The other office-bearers for the year were appointed as follows: Vice-President, Dr. Harry Rainy; Councillors, Drs. John W. Ballantyne, John Macpherson, George M. Robertson, Robert Thin, and James Lamond Lackie; Treasurer, Dr. Norman Walker; Secretary, Dr. J. S. Fowler; Hon. Librarian, Dr. John William Ballantyne; Curator of the Research Laboratory, Dr. J. J. Graham Brown.

Sir E. Coey Bigger has been nominated a member for Ireland of the General Medical Council for a further period of five years from Jan. 24th, 1922.

University of Manchester.—Prof. H. B. Dixon, F.R.S., who as successor to Sir Henry E. Roscoe has occupied for 35 years the Sir Samuel Hall Chair of Chemistry in Owens College, and later in the University of Manchester, has intimated to the Council and Senate of the University his intention to retire at the end of the present session. Prof. Dixon's special line of investigation has been the rate of explosion of gases, and for his work in connexion with the inspection of explosives during the war he was awarded the C.B.E. Prof. Dixon intends to continue his researches in the chemical department of the University.

The following appointments to the University of Manchester have been made: Mr. J. P. Buckley, lecturer in regional surgery; Mr. J. M. W. Morison, lecturer in applied anatomy; Dr. T. H. Oliver, lecturer in clinical medicine.

Glasgow Victoria Infirmary.—At the annual general meeting of contributors to the Glasgow Victoria Infirmary on Dec. 1st, Mr. William Gray, the chairman, said that the daily number of cases now averaged 283. This was more than the present building could properly accommodate, but in view of the cost of building and the additional expenditure for maintenance involved, the governors hesitated to proceed with extensions. They had received substantial support from the public during the past year and the large increase in employees' subscriptions was most gratifying; if the scheme drawn up last year was universally adopted, he thought they might rely on a further increase from this source. The thirty-fourth annual report, recently issued, showed that during the year 4348 patients were treated, exclusive of 1917 cases of accidents and minor surgical ailments, and at the electrical department there were 9195 attendances. The cost per patient was £10 9*s.* 3*d.*, as against £10 4*s.* 3*d.* last year, and the cost per bed £160 14*s.* 5*d.*, compared with £159 9*s.* 2*d.* At Bellahouston Dispensary 24,560 patients were treated, and they had had to draw a sum of £1157 from the infirmary to meet expenses; and in the home at Largs, where 498 patients were treated, they had also had to draw on the infirmary funds. Including both legacies and special donations, they had an income of £60,295 this year, leaving a surplus over expenditure of £6356, which had been carried to capital, compared with a deficit of £1511 drawn from capital the previous year.

Maudsley Hospital Course for Diploma of Psychological Medicine.—The first part of the fourth course of lectures and practical courses of instruction for this diploma will begin on Jan. 3rd, 1922, at 2.30 P.M. Sir Frederick Mott, F.R.S., will give the first of eight lectures on the Anatomy of the Nervous System. He will also give practical instruction and demonstrations on methods of staining nervous tissue and preparing it for microscopical examination, on the living nerve cell and the nerve fibre, on degeneration and regeneration of nerves, and will distribute sections, illustrating the principal diseases of the nervous System, for mounting as a permanent collection. On Jan. 6th, at 2.30 P.M., Dr. F. Golla will give the first of eight lectures on the Physiology of the Nervous System, including practical instruction and demonstrations on physiological chemistry and practical physiology. On Jan. 5th, at 2.30 P.M., Dr. Henry Devine will give the first of eight lectures on Psychology, including practical instruction and demonstrations on sensation, psycho-physical methods, statistical methods, reaction times, association, memory, intelligence tests, muscular and mental work. The second part of the course will follow in April, 1922, and will include lectures and demonstrations on (1) The Diagnosis, Prognosis, and Treatment of Mental Diseases; (2) Mental Defect and Crime; (3) The Practical Aspect of Mental Deficiency; (4) Pathology of Mental Diseases, including Brain Syphilis, its Symptomatology and Treatment; (5) The Symptomatology of Mental Diseases; (6) The Psychoneuroses; (7) Demonstrations in Neurology. The fee for the whole course is £15 15*s.*, and for each part separately, £10 10*s.*; for one single series of lectures in Part I., £4 4*s.*; for one single series of lectures in Part II., £2 2*s.* The Fellowship of Medicine, 1 Wimpole-street, London, W., will collect fees from, and issue admission tickets to, medical men intending to take the course who are introduced by the Fellowship. Inquiries as to lectures, &c., should be addressed to the Director of the Pathological Laboratory, Maudsley Hospital, Denmark Hill, S.E.

An Address
ON THE RELATIONSHIP OF URÆMIA AND HYPERPIESIA.

Delivered at a Meeting of the Bradford Medico-Chirurgical Society on Oct. 5th, 1921,

By H. BATTY SHAW, M.D., F.R.C.P. Lond.,
PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL AND TO THE BROMPTON HOSPITAL FOR DISEASES OF THE CHEST.

THERE can be no necessity for apology in venturing to discuss these two conceptions—uræmia, an old and familiar one, and hyperpiesia, so new that it has not yet appeared in books of reference—because it is apparent that there is a relationship between them. They seem to mean the same thing in many particulars, yet not in all.

I. The Conception of Uræmia.

Before the propositions put forward in this address are developed, it is necessary to know the present views on the clinical and pathological significance of the term uræmia. In conditions of health urea is present in the blood to the extent of a quarter to half a gramme in every 1000 g. of blood; in this sense, therefore, uræmia is physiological. There are also numerous clinical conditions in which urea of the blood is increased in amount: in some cases, but not all, there is kidney disease. Moreover, the occurrence of certain well-known symptom-complexes leads us to suspect kidney disease; we speak of these symptom-complexes as manifestations of uræmia—an incorrect designation, inasmuch as it signifies the presence in the blood of urea in excess of the physiological amount, and assumes that this excess is responsible for production of the symptoms called uræmia. It is now admitted that an excess of urea in the blood is not the cause of uræmic symptoms. The wonder is that the expression should still be used by clinicians when our pathological and experimental brethren have shown that uræmia is a misnomer. Clinicians need some special expression to fix the identity of the curious bed-side manifestations described as uræmia; but it is regrettable that so far no more suitable term has been coined to take its place. It is possible now, however, to replace the expression uræmia—a condition hitherto unexplained—by another word which commits no one using it to any particular new theory of causation. Any such proposed change will certainly meet with resistance; indeed, one authority has already said that it would be futile and pedantic to attempt to abolish the word uræmia, although neither urea nor any known element present in the urine, nor urine itself taken as a whole, has been shown to be capable of producing the toxic effects which the term uræmia covers. Before the current definitions of uræmia are studied, it will be found not uninteresting to trace the stages by which the term was introduced.

Growth of Knowledge Concerning Urea.

It is not quite clear whether the discovery of urea was made by Rouelle or by Cruickshank towards the end of the eighteenth century. As early as 1822 Vauquelin and Ségalas D'Etchepare[1] studied the toxic effects of the introduction of urea into the veins of an intact animal. They found no harmful effects; they experimented further on the same animal by injecting 3 oz. of urine into its veins, and it died in a few minutes from widespread clotting of the blood. In 1827 Bostock[2] examined the serums of some of Bright's dropsical albuminuric patients; besides establishing the fact that these serums contained less albumin than those of healthy people, he also found a substance present which resembled urea, and he states that Dr. Prout had found this substance in a dropsical patient six months earlier. Christison[3] in 1829 went a stage further and found that in the serums of patients suffering from dropsy and albuminous urine, dependent upon kidney disease, there was a large quantity of urea. Up to this date investigations had merely shown at the hands of these workers what we know nowadays to be the rule, that urea is present in the blood in health, and may be decreased and increased in health and in disease, but no one had come forward with the idea that the urea present in the blood in cases of dropsy and albuminous urine, dependent upon kidney disease, was the cause of the various toxic symptoms met with in these conditions, until Dr. James Arthur Wilson[4] delivered an address before the Royal College of Physicians in 1833 on "Fits and Sudden Death in connexion with Disease of the Kidneys." He surmised that these manifestations were due to the blood altered by disease of the kidneys. These are his actual words: "The exact change of the blood may require further investigation, but the presence of urea and the deficiency of albumen are those which hitherto chiefly attracted the notice of Dr. Prout and Dr. Bright." Wilson's object was to insist on the "intimate, constant and vital connexion of brain, lungs and heart with the kidneys through the medium of the blood." These remarks uttered by Wilson are generally acknowledged to constitute the first recorded suggestion that urea present in the blood might cause some of the symptoms in Bright's disease. Thus, so long ago, one observer felt that the blood contained toxic principles in cases of Bright's disease. Within a few years of Bright's discovery the poisonous condition of the blood in the cases he described began to be thought of; this is an important point. It is material to this address that to this day it is not known what those poisons are, although urine, urea, and other renal excreta are certainly not the sources of the poison.

Introduction of Term "Uræmia."

Some observers think that the birth of the idea that an accumulation of urea in the blood in cases of Bright's disease is the cause of the toxic symptoms of that disorder is to be found rather in the writings of Robert Willis[5] than in the above remarks of Wilson. Willis said, "All we know would, therefore, lead us to infer, that in the dangerous form of albuminous urine either the formation of urea, wherever this takes place, was suspended, that it was not duly separated from the blood by the kidney, or that," &c. So far, the term uræmia had not been used; according to Marfan[6] we owe the introduction of the word into medical literature to Piorry, who, according to Fournier (De l'urémie: Fournier, Thèse d'agrégat. de Paris, 1863), first used this term in 1847. Frerichs[7] in 1851 discussed "uræmic intoxications." From those times to the present most authorities have continued to use the word uræmia as expressive of the toxic symptoms produced by the blood which has been altered by disease of the kidneys. Observers had before them the clinical records of Richard Bright's 23 cases, and they had before them the coloured plates representing the kidneys met with in those cases. It must be remembered, of course, that in those days there was no microscopic examination of the organs illustrated.

The Three Groups of Bright.

It is now necessary to draw attention to the following quotations from Bright's paper (loc. cit., p. 67). Speaking of the several forms of disease to which the kidney became liable in the foregoing dropsical affections, he thought there were three varieties, if not three completely separate forms of diseased

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MEETINGS OF SECTIONS.

Tuesday, Dec. 20th.

GENERAL MEETING OF FELLOWS: at 5 P.M. Ballot for Election to the Fellowship. (Names already circulated.)

Wednesday, Dec. 21st.

HISTORY OF MEDICINE: at 5 P.M. *Papers:* Mr. C. J. S. Thompson: The Parturition Chairs, their History and Use. Miss Eileen Power: An English Woman Doctor in the Fifteenth Century.

OBSTETRICS AND GYNÆCOLOGY. Members of this Section are specially invited to attend the Meeting of the History Section announced above.

LONDON DERMATOLOGICAL SOCIETY, 49, Leicester-square, W.C.

Tuesday, Dec. 20th.—4.30 P.M., Pathological Specimens. Cases sent for Consultation. Clinical Cases. 5 P.M., Address by Dr. Harry Campbell: The Disorders of the Cutaneous Circulation. 7 P.M., Fellows' Monthly Dinner. Cavour Restaurant, Leicester-square. Tickets 6s. 6*d.* each. Dr. Mitchell, 33, Weymouth-street, W., should be notified at or before the Society's Meeting.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.

Monday, Dec. 19th.—2 P.M., Mr. Addison: Visit to Surgical Wards.

Tuesday.—2 P.M., Dr. Pernet: Skin Department.

Wednesday.—10 A.M., Mr. MacDonald: Genito-Urinary Department.

Thursday.—2 P.M., Mr. Bishop Harman: Eye Department.

Friday.—2.30 P.M., Dr. Pritchard: Visit to Medical Wards.

Saturday.—10 A.M., Dr. Arthur Saunders: Medical Diseases of Children.

Daily:—10 A.M., Visit of Post-Graduates to Wards. 2 P.M., In-patient, Out-patient Clinics and Operations.

MANCHESTER ROYAL INFIRMARY POST-GRADUATE CLINIC.

Tuesday, Dec. 20th.—4.30 P.M., Mr. J. P. Buckley: Vague Abdominal Symptoms.

Appointments.

Cornelius, J. T., has been appointed Assistant Professor of Hygiene at the Provincial Institute of Hygiene and Sanitation, Lucknow.

Maclean, Ewen J., M.D., C.M. Edin., M.R.C.P. Lond., Professor of Obstetrics and Gynæcology in the University of Wales in connexion with the Welsh National School of Medicine, Cardiff.

Ord, J. W. E., M.D., C.M. McGill, Certifying Surgeon under the Factory and Workshop Acts for Eyam.

Walker, K. M., F.R.C.S. Eng., Surgeon with charge of Out-patients, Great Northern Central Hospital.

Hampstead General Hospital: Semon, H. C., M.D., B.Ch. Oxon., Dermatologist; Booth, L. H., M.B., Ch.B. Dunedin, N.Z., House Surgeon: Fanning, J., M.B., B.S. Lond., House Physician; Warde, Mildred, M.R.C.S., L.R.C.P. Lond., Casualty Medical Officer; Collie, Alison Margaret, M.B., M.R.C.S., L.R.C.P. Lond., Casualty Surgical Officer.

The Queen's Hospital for Children, Hackney-road: Russell, H. B., B.Ch. Camb., F.R.C.S. Eng., and Braithwaite, J. V. C., M.B., B.S. Lond., Assistant Physicians.

Vacancies.

For further information refer to the advertisement columns.

Ashton-under-Lyne District Infirmary.—H.S. £200.
Barry Accident and Surgical Hospital.—S. £750.
Bath, Winsley Sanatorium.—Asst. Res. M.O. £250.
Bedford County Hospital.—Asst. H.S. £150.
Birmingham, Ministry of Pensions, Orthopædic Centre.—Res. Surg. O. £300.
Birmingham, Queen's Hospital.—Obst. and Ophth. H.S. and Cas. H.S. Each £90.
Birmingham, Rubery Hill and Hollymoor Mental Hospital.—Jun. Asst. M.O. £400.
Blackburn County Borough.—Asst. M.O.H. £600.
Brighton, Royal Sussex County Hospital.—Hon. P. and Hon. Asst. P.
Bristol Royal Infirmary.—H.P. and H.S. £120 each.
Bury Infirmary.—Jun. H.S. £150.
Bury St. Edmunds, West Suffolk General Hosp.—Res. H.S. £200.
Cambridge, Addenbrooke's Hospital.—H.S. £130.
Cape Town University.—Tech. Asst. in Surgery. £350.
Chester, Cheshire County Council.—Dist. Tub. O. £600.
City of London Hospital for Diseases of the Chest, Victoria Park.—Res. M.O. £250.
Derbyshire County Council.—Sanat. Supt. £700.
Dorchester, Dorset County Council.—Asst. M.O. £500.
Dover Borough.—Asst. M.O.H. £750.
Dover Royal Victoria Hospital.—H.S. £180.
East Ham County Borough Education Committee.—Asst. Sch. M.O. £500.
Exeter, Royal Devon and Exeter Hospital.—Sen. H.S. £250. Asst. H.S. £150.
Great Northern Central Hospital, Holloway-road, N.—Res. M.O. £250.
Hospital for Diseases of Throat, Golden-square.—Hon. Asst. S.
Hospital for Sick Children, Great Ormond-street.—Cas. O. £400.
Inverness Northern Infirmary.—H.S. £150.
Johannesburg, University College.—Sen. Lect. in Anat. £516.
Leeds Hospital for Infectious Diseases, Seacroft.—Second Asst. M.O. £250.
Leeds Public Dispensary.—Sen. Res. M.O. £250.
Lincoln, Bracebridge Mental Hospital.—Med. Supt. £750.
London Homœopathic Hospital, Bloomsbury.—M.O. for X ray Dep.
London Lock Hospital, 91, Dean-street.—Clin. Assts.
Macclesfield General Infirmary.—Sen. H.S. £200.
Manchester, Baguley Sanatorium.—Med. Supt. £500.
Manchester Royal Infirmary.—Asst. M.O. £35.
National Hospital for Diseases of Heart, Westmorland-street.—Res. M.O. £150.
Putney Hospital.—Hon. Surg.
Royal College of Physicians, Pall Mall.—Milroy Lect.
Royal Free Hospital, Gray's Inn-road.—H.P. £50.
Royal Naval Medical Service.—Surg. Lieuts.
Royal Waterloo Hospital for Children and Women, Waterloo-road. Radiographer. £100.
Russian Famine Friends' Relief Committee.—Doctors wanted.
St. Bartholomew's Hospital.—Asst. Aural S.
St. George's Hospital, S.W.—Res. H.P.'s and H.S. Each £50.
St. Pancras Metropolitan Borough.—Tuberc. O. £818 18s.
Sheffield Royal Infirmary.—Cas. O. £150.
Shrewsbury, Royal Salop Infirmary.—H.S. £275.
Southport General Infirmary.—Jun. H.S. £175.
Staffordshire General Infirmary.—H.S. £250.
Ventnor, Royal National Hospital for Consumption.—Asst. Res. M.O. £300.
West London Hospital, Hammersmith-road.—Two H.P.'s and one H.S. Each £100.
Winchester, Royal Hampshire County Hospital.—H.S. £150.
Windsor, King Edward VII. Hospital.—Asst. in X ray Dept.

The Secretary of State for the Home Department, S.W., gives notice of a vacancy for a Medical Referee under the Workmen's Compensation Act, 1906, for County Court Circuit No. 49, attached more particularly to the Margate and Ramsgate County Courts. Applications should reach the Private Secretary, Home Office, S.W., not later than the 28th December.

Births, Marriages, and Deaths.

BIRTHS.

Cripps.—On Dec. 7th, at Lower Seymour-street, W., the wife of W. Lawrence Cripps, F.R.C.S., of a son.

Edwards.—On Dec. 11th, at Camberwell House, the wife of Dr. Francis Edwards, of a son.

Rankin.—On Dec. 9th, at Harley-street, the wife of Nicol M. Rankin, M.C., M.B., Ch.B., of a son.

Vincent.—On Dec. 5th, at Old Court, Ealing, to Dr. and Mrs. L. J. Vincent, 6, Twyford-crescent, Acton—a son.

MARRIAGES.

Driberg—Carter.—On Dec. 2nd, at St. Marylebone Parish Church, James D. Driberg, O.B.E., M.C., F.R.C.S., Queen Anne-street, to Dorothy Unwin Carter, daughter of the Rev. Arthur and Mrs. Carter, of Thrussington, Leicester.

Lindsay—Davis.—On Dec. 3rd, at St. John's Church, Ladbroke-grove, E. Charles Lindsay, C.B.E., F.R.C.S., to Mrs. M. C. Davis, of Undercliff, St. Margaret's Bay.

Rees—Hemingway.—On Dec. 15th, at Regent-square Presbyterian Church, London, by the father of the bridegroom, assisted by Rev. Herbert Gray, John Rawlings Rees, M.D., of 146, Harley-street, third son of Rev. R. M. Rees, M.A., and Mrs. Rees, of Epping, to Mary Isabel Hemingway, M.B., Ch.B., second daughter of Charles R. Hemingway, J.P., C.B.E., of Penrhyn House, The Park, Nottingham.

DEATHS.

Coleman.—On Dec. 11th, at Dunedin, Surbiton, Matthew Owen Coleman, M.D., D.P.H., aged 77 years.

Dilworth.—On Dec. 4th, after a short illness, Timothy Francis Moya Dilworth, M.B., M.Ch., B.A.O. N.U.I., Senior Demonstrator of Anatomy at St. Thomas's Hospital; aged 28 years.

Frost.—On Dec. 10th, Edmund Frost, M.D., of Chesterfield Meads, Eastbourne, aged 64 years.

Palmer.—On Dec. 7th, at Oakley-street, S.W., after a short illness, James Foster Palmer, M.R.C.S., L.R.C.P., aged 73 years.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

signs and symptoms and the actual diseased condition of the kidneys to altered condition of the blood from some infection, whether chronic or not—e.g., syphilitic toxæmia and various bacterial toxæmias.

4. But just as in syphilis all infected cases do not show kidney disease, albuminuria, dropsy, and other toxic signs and symptoms, so also infections producing *changes in the blood do not show, in all cases*, the complete pictures above sketched; in some dropsy alone occurs, or albuminuria alone occurs, or the other toxic symptoms met with in so-called uræmia alone occur (to the exclusion of albuminuria and of dropsy); in still others, changes occur only in the kidney, to the exclusion of albuminuria or of dropsy or of both, or of the other signs and symptoms of so-called uræmia.

Definition of Uræmia.

At last, after a rather long preparation, the definition of uræmia so-called, may be given thus: It is a clinical expression which seems to indicate a condition in which the blood is so altered by disease, especially —possibly exclusively—by infections; that changes may occur in the kidneys; that plasma proteins may no longer be retained within the capillaries, &c., owing to leakage through the damaged capillary walls (hence albuminuria, anasarca, and œdema of the lung); that irritation or paralysis may affect the cortex cerebri (hence fits and mania, local or general motor palsies, blindness, deafness, coma, &c.), or the respiratory centres (hence renal asthma or periodic breathing), *or may affect the neuro-muscular control* of the heart and blood-vessels (hence alteration in the pulse-rate, asystole, "sudden death," &c.), or may affect the gastro-intestinal tract, producing vomiting and diarrhœa, &c. When the kidneys are seriously damaged, then urea, uric acid, and various other crystalloids may be reduced in amount in the urine, and increased in amount in the serum, depending on the failure of the kidneys to act properly—i.e., if not depending upon less intake of nitrogenous food from nausea or loss of it by vomiting, and if the liver is healthy. If the kidneys are not damaged or not seriously damaged, then such change in the urea of the urine or blood may not be observable. When dropsy is a feature there may be concentration of the plasma owing to loss of water, and if albuminuria is excessive there may be a loss of proteins in the plasma.

It will be seen that this definition accounts for those conditions possibly occurring in Bright's first group already referred to when the kidneys were only, *as it were, on the way to the eventually advanced* state in which dropsy and albuminuria would occur, and met with by Cruickshank, Wells, Graves, and Willis, and by numerous observers since in cases in whom the kidneys were not diseased at all, or if the parenchyma were diseased showed no albuminuria or no dropsy, or showed the latter two phenomena without being diseased, or showed parenchymatous change with or without the other toxic symptoms met with in so-called uræmia.

But how will such a definition apply to those cases in whom so-called uræmia is met with in those who are subject to granular kidneys? It is well known that granular kidneys may be found, even in an advanced stage, in apparently healthy patients who have died from accident or from some disease quite independent of renal disease; *therefore in cases of* granular kidney showing uræmic (?) symptoms and signs these latter are not due to the granular kidney, but still are referable to a toxic blood state, though in such cases the cause of the toxic blood state is not known. It may be also the cause of the degeneration of the kidneys, whether this is apparently due to vascular disease (for even this must be a blood-borne disease—e.g., as a result of bacterial infection or of syphilis) or is due to capsulitis with successive tubular degeneration, which also must be blood-borne. The toxic state of parenchymatous kidney disease is almost identical in features with that of so-called granular kidneys, though it may be more acute and more remediable in the former, and more chronic and irremediable in the latter.

If the kidney is sufficiently damaged, then anuria may be an added feature, death subsequently occurring from a continuation of the toxic effects of the blood-borne poison, as a rule in three or four days, or a week.

But supposing there is no blood-borne poison at work and anuria occurs from obstructive suppression of the urine or from acute thrombosis of the renal arteries, then how does uræmia express itself? As is well known, little or no uræmia develops at all, and death does not occur for 7 to 11 days, or may be a fortnight. It is not known for certain why death should occur in such cases, but it is possible that the ultimate cause is due to the accumulation of retained unexcreted metabolites, which, as has been shown, are quite unable to produce dropsy or any other of the toxic symptoms of so-called uræmia, but which may quite readily produce vascular paralysis and such low blood pressure that the heart becomes defeated; or it is possible that cellular changes occur throughout the body which has suffered from anuria so long, and that as a result histamine-like bodies are liberated and cause death by dilatation of the capillaries of the body.

Contemporary Definitions of Uræmia.

Having developed this definition of so-called uræmia as a state due to pre-renal toxæmia—which seems so readily to explain the pathogenesis not only of the *intrinsic kidney disease, but also of all the attendant* symptoms and signs—it is with feelings of hesitation that I now quote the definitions which we owe to contemporary well-known authorities.

> "Uræmia is a state of toxæmia *dependent* upon insufficiency *of the kidneys which may develop in the course* of nephritis or in conditions associated with anuria."[15] "Uræmia is a name given to a group of symptoms which *occur* in nephritis (and in granular kidneys, see context)."[16] "The name uræmia is used for a group of symptoms *arising* during the course of many renal diseases dependent mainly, *but not entirely, upon derangement of the nervous system.*"[17] "The name uræmia is used to designate a group of symptoms which *usher* in the fatal ending in a large proportion of cases of renal disease."[18] "Uræmia may be related to nephritic hypertension."[19] Richard Stern,[20] writing on diseases of the urinary organs, says that "*if the kidneys do not carry out their work well from actual disease or severe functional disorder*, there will *result* very frequently a symptom-complex *which is spoken of as uræmia.*" Nothnagel[21] says that "uræmia is an auto-intoxication *brought about by the retention* not of one excretion, but by all or several constituents of the urine. The nitrogenous end-products may produce the poisonous effects after decomposition in the body."

A careful examination of these definitions will show that the attitude of the various authorities quoted is not identical—they do not all insist that uræmia is caused by retention of metabolites from grave disease of the kidney; some admit that purely functional disease of the kidney may be the cause, which is another way of saying that kidneys showing no organic disease may be associated with the development of uræmic symptoms; others say that uræmic symptoms are associated with kidney disease, but it is left to the reader to discover what the association is; it may be the one already given—viz., that the kidney change and the toxic symptoms are results of a common cause. Further, no one insists that uræmia does *not occur except in kidney disease, nor* that kidney disease is necessarily followed by or associated with any of the manifestations of uræmia.

PLANT RESPONSE TO INJURY.

At a meeting of the Association of Economic Biologists, held on Dec. 9th in the Botanical Lecture Theatre of the Imperial College of Science, South Kensington, Sir David Prain presided over a discussion on the Resistance of Normal and Injured Plant Surfaces to the Entry of Pathogenic Organisms. Prof. J. H. Priestley, of Leeds, who opened the discussion, pointed out the important bearing of certain research work now being carried out in his laboratory. He described the structural features of the normal plant which opposed the entry of pathogenic organisms and the chemical response made by the plant tissue to injury. The surface of a cut potato tuber within a short time of injury became covered by a layer of "suberin" arising from the oxidation and condensation of fatty substances mainly carried to the cut surface by the sap. Similar deposits might be traced in the normal tissues of root, stem, and cuticle. Suberisation took place just below the cut surface, the depth varying with the conditions and the nature of the plant. In the potato the fatty substances appeared to come from the greater part of the tissue and to be carried to the surface by vascular strands. At a later stage a meristem arose beneath the blocked surface and gave rise to cork tissue running across the wounded surface. A study of the conditions under which cork was formed might, Prof. Priestley concluded, throw light upon many problems relating to injury of tissues.

ARMENIAN REFUGEES (LORD MAYOR'S) FUND.

To the Editor of The Lancet.

Sir,—I am anxious to obtain the greatest possible support for the appeal being made this Christmas-time by the Armenian Refugees (Lord Mayor's) Fund, of which I am President. While other nationalities are enjoying opportunities for recovery and reconstruction after the war, the Armenian nation has none. At no time in her history has her need been greater. Owing to Turkish invasion the Armenian Republic of Erivan was unable to sow in time for a harvest and famine is already widespread. It is calculated that 180,000 children, many of them orphans, and 120,000 adults, are already on the verge of starvation, and by the end of January there will be no foodstuffs available except those provided by relief agencies. In addition to this vital emergency work, the Fund is responsible for an orphanage of some 600 children near Constantinople, and has felt obliged a few days ago to offer to undertake the care of 300 more. These are the purposes for which I appeal most earnestly to the public. Donations should be sent to the Hon. Treasurer, Lord Mayor's Fund, 96, Victoria-street, S.W. 1.—I am, Sir, yours faithfully, John Baddeley,

Mansion House, E.C., Dec. 8th. Lord Mayor of London.

YEAR-BOOKS.

The thirtieth edition of the *Annual Charities Register and Digest* (London: Longmans, Green and Co., for the Charity Organisation Society, pp. 599+xx., 7*s.* 6*d.*) is described on the title-page as "a classified register of charities in or available for the metropolis," but presumably this description is only intended to indicate that the information concerning London charities is practically exhaustive, whereas that which concerns provincial, Scots, Irish, colonial, and foreign institutions is less detailed; indeed, it is pointed out at the commencement of the colonial and foreign list that owing to existing circumstances it has been found impossible to revise the Continental list. The financial review of the year, with which the volume opens, bears witness to the magnitude of the task of preparation and the difficulties involved in assembling statistics at once simple and comprehensive; for instance, the impossibility of separating London and provincial charities is evidenced in the case of Dr. Barnado's Homes among other institutions; and there are important establishments—e.g., many of those supervised by the Roman Catholic Church, and some Anglican sisterhoods—to which considerable sums are contributed, but which do not furnish statistics in the same way as do purely secular institutions. The review of the year is divided into eight sections: the first comprises details of the London Charity Organisation Society, a list of societies throughout the United Kingdom which correspond with that society, and the foreign and colonial list already referred to. The sections devoted to Relief in Affliction, in Sickness, in Distress (permanent and temporary), and Reformatory Relief, suggest the contents by their titles; a miscellaneous section includes information concerning social and physical improvement, emigration, &c., and one section is devoted to Spiritual Institutions. Useful appendices deal with benevolent institutions, friendly and trade societies, registry offices attached to charitable institutions, metropolitan labour exchanges, and guilds of help, and provide other information difficult to obtain elsewhere.

The publishers of the *Official Year-Book of the Scientific and Learned Societies* (London: Charles Griffin and Co., 1921, pp. 366) state that this thirty-eighth annual volume retains all the valuable features of previous issues, and that every effort has been made to maintain a high degree of accuracy. The book is a record of the work done in science, literature, and art during the session 1920–21 by numerous societies and Government institutions, and since it is compiled from official sources the information is in the main accurate and comprehensive. We note among minor errors that the name of the president of the Harveian Society is wrongly spelt, and that the list of papers stated to have been read between October, 1920, and March, 1921, at St. Mary's Hospital Medical Society is actually the programme for the current session 1921–22. The volume is well arranged, of small bulk, and has a good index.

The *Girls' School Year-Book* (*Public Schools*) (London: H. F. W. Deane and Sons, The Year-Book Press, Ltd., 1921, pp. 574, 7*s.* 6*d.*) is issued as the official book of reference of the Association of Head Mistresses. The greater part of the book is taken up with a list of the public secondary schools for girls, with details of personnel of governing body and staff, fees, special features, and so forth. Part II. deals mainly with the future careers of girls leaving school. Those contemplating medicine as a career will find condensed into two pages an admirable summary of the points to be considered in the choice of a medical school and of a degree or diploma, of the prospects offered to women entering the medical profession, and other practical suggestions. The list of metropolitan medical schools open to women is incomplete.

TRAVELLING PUBLIC HEALTH INSTITUTES.

In an annotation in our issue of Dec. 10th attention was drawn to the new schools of public health recently endowed at Johns Hopkins and Harvard Universities. One of the most successful activities of the first of these schools during the winter of 1920 was a special six weeks' course of instruction for public health workers and officials, which was largely attended by medical and sanitary officers from many States within the union, as well as by others from Canada and Central and South America. The need for short intensive courses of instruction for public health workers is evidently being more fully realised; and we have before us the preliminary announcement of a series of "Public Health Institutes" which are being organised in 21 cities in various States by the United States Public Health Service. These institutes are one-week schools, at which addresses and demonstrations of special types of public health work are given. The syllabus of these courses is ambitious, embracing some 57 lectures on 15 subjects, though obviously selection will be made in different areas. The New Orleans Institute, which begins on Jan. 9th, will include the following courses: tuberculosis, nutrition in health and disease, general communicable diseases, industrial hygiene, administrative problems, medical social work, protective social work, child hygiene, the management of clinics and health centres, non-communicable diseases, sanitary engineering, mental hygiene, the delinquent, syphilis, and gonorrhœa. Did we not know the marvellous assimilative power of Americans for lectures, the carrying out of such a syllabus might be expected to cause acute mental dyspepsia; but in that country this result need not be feared. The general result of these courses of instruction will be to increase local interest in public health problems, to stimulate the discouraged workers, and to secure valuable interchange of thought and experience between teachers and students and between individual workers. The courses, as is carefully pointed out in the prospectus, cannot take the place of more detailed training for public health work. They will, however, point to the importance of such training, and stimulate attendance at the schools where it is given. The experiment is one to be watched with interest, for its own sake as for its bearing on possibilities of similar courses in this country.

there was a ready explanation for the increase in the heart weight. But it will be objected that in Case A part of the cardiac increase of weight was due to the presence of kidney disease (a common clinical association), as shown by the microscopic changes present in the kidney and by the occurrence of uræmic attacks. But what slight changes in the kidney were present in this case! They were probably no more than can be found in the kidneys of healthy individuals who have died of some accident, and they were almost identical with those found in Case B, who did die of an accident—a cerebral hæmorrhage and not of uræmia; therefore any increase of the weight of the heart in Case A, which was not due to the mitral disease, was not due to kidney disease, nor were the uræmic attacks due to the kidney disease. In Case B the heart was found to be greatly enlarged from hypertrophy, and the kidneys showed small change, and it may be conceded that if the earlier attacks of coma and convulsions were uræmic, they also were not due to kidney disease. The question now presents itself for solution, what was the cause for the cardiac hypertrophy and the uræmic manifestations present in these two cases? It has been admitted that mitral disease was present in Case A, and accounted for part of the cardiac hypertrophy: an unexplained residuum is left. These phenomena were not due to kidney disease. I will offer an explanation after consideration of the following two cases:—

CASE C (Fig. 3).—A man, aged 79 years, who had not worked for several years. He was admitted to hospital for shortness of breath on the least exertion, for cough, for palpitation and pain over the heart, and for dropsy of the body and legs.

The brachial artery was *tortuous*; *the pulse irregular*; the maximum impulse of the heart was present in the sixth intercostal space, external to the left nipple-line, and was heaving in character; there was an apical systolic murmur; the liver was enlarged; albuminuria was present on three examinations and absent on one; the temperature was normal throughout his stay in the ward. Death was sudden, and the clinical diagnosis of the cause was cardiac failure.

FIG. 2.

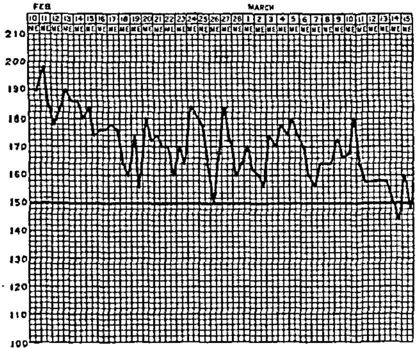

FIG. 2A.

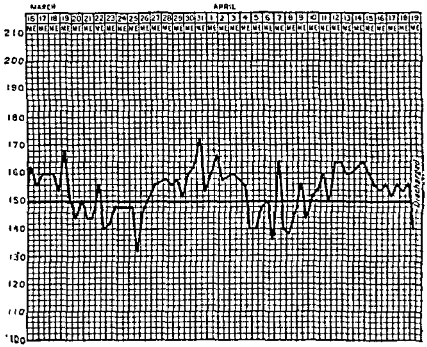

FIGS. 2, 2A, 2B (Case D).—Charts drawn up as results of two separate visits to hospital.

FIG. 2B.

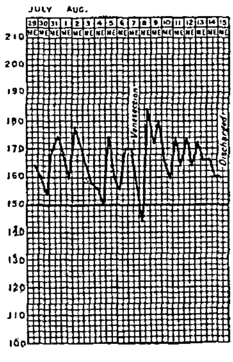

FIG. 3.

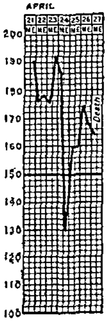

CASE C.—Chart of a few days' observations.

CASE D (*Figs.* 2, 2A, 2B).—*A coach-builder (woodwork only)*, aged 42 years. This man had suffered from shortness of breath, from palpitation and "night starts," from *dropsy and from cough, which led to the expectoration of* white, frothy material streaked with blood; he had been in the habit of getting up at night to pass water. He had had syphilis, for which he had been treated with mercury continuously for 15 months. He had been admitted to the hospital on three separate occasions, always with the same symptoms, except that on the last admission he had noticed that he was passing very little water. He was a stout, healthy-looking subject; the maximum impulse was present in the fifth intercostal space in the left anterior axillary line; there was a loud systolic murmur at the maximum impulse; rhonchi were heard over both lungs; there were *dropsy and ascites and the liver was enlarged*; the temperature as a rule was normal, but on a dozen occasions was raised a little over 99°; the urine was frequently examined, and always showed albumin; casts were found in the urine, and hæmaturia occurred on several occasions; dyspnœa and cyanosis became so great that he was venesected with considerable relief; ultimately a presystolic murmur was heard at the maximum impulse. The pulse was irregular, but electro-cardiographic observations favoured the view that this was due merely to functional, not organic, defect of the right branch of the auriculo-ventricular bundle; the brachial arteries were *tortuous*. Death occurred gradually with marked dyspnœa. The blood taken during life gave a positive Wassermann reaction.

In passing comment on Case C, it looks as if this old man had simply died from heart disease, the lesions being leakage of the mitral valve and disease in the conducting fibres of the heart wall. The usual features of cardiac failure developed and the sudden death was explainable on the ground that possibly auricular fibrillation had closed the scene. Case D was another example of illness due to heart disease, and the presence of syphilis suggested that this disorder had damaged the mitral valve, producing a characteristic double murmur and changes in the heart muscle, leading to failure of compensation as shown by dropsy, enlarged liver, albuminuria, &c.,

structure, generally attended by a decidedly albuminous character of the urine.

> "In the first, a state of degeneracy seems to exist, which from its appearance might be regarded as marking little more than simply debility of the organ. . . . I have found it in a case of diarrhœa and phthisis and in a case of ovarian tumour. In the former it was connected with slight and almost doubtful coagulation of the urine by heat; in the latter I had omitted to examine the state of the urine. . . . When this disease has gone to its utmost it has appeared to terminate by producing a more decided alteration in the structure. . . . . In this more advanced stage, if it be the same disease, dropsy has existed and the urine has been coagulable."

On p. 69 (loc. cit.) Bright says :—

> "Although I hazard a conjecture as to the existence of these three different forms, I am by no means confident of the correctness of this view. On the contrary, it may be that the first form of degeneracy to which I refer never goes much beyond the first stage."

The first of Bright's three groups is of special interest. As already observed, the kidneys were not subjected to microscopic examination; Bright admitted that albumin was not demonstrated in the urine of all the cases, and he also admitted that the degeneracy observed might after all be simple debility of the kidney. While still speaking of this first group, he admitted that the kidneys belonging to this group might mean progress to later stages, and finally he says that when the disease had gone to its utmost, dropsy and albuminous urine became features, from which it may be inferred that there need be no surprise if in this first group such signs were not present. To these points reference will be again made later on. At the present day there is scarcely any dissent from the view which followed upon Bright's work that certain cases of dropsy and albuminuria are dependent upon kidney disease, and that the other attendant signs and symptoms of these cases are due to poisons present in the blood; no one, however, can say what is the nature of the poisons present except in the negative sense that they are not renal excretions retained owing to loss of power of the damaged kidneys to excrete them.

To return to the years which followed Bright's discovery, other observers were to be found who seemed to agree with Bright as to the slight change in the kidney which may be found in cases of dropsy and albuminuria. Willis,[8] speaking of cases of albuminous urine who showed symptoms always serious and often irresistibly fatal, said this form

> "of albuminous urine appears to be connected with a positive alteration in the structure of the kidneys, or *with a state the tendency of which is to end in this*, . . . as accompanying the general dropsical condition of the cellular membrane and serous condition, which is characterised as anasarca."

It is apparent from perusal of Willis's book that a group of writers, including himself, kept an open eye upon the possibility that although many cases of albuminuria and dropsy revealed disease of the kidneys as well, it was not disease of the kidney *per se* which, by alteration of the blood, caused the signs and symptoms met with in such cases. The following passage will be found to be full of interest. Willis[9] wrote :—

> "With regard to the pathology of the simple albuminous urine, especially of that which occurs along with general dropsy, opinions are at present very much divided. Whilst some (Bright, Gregory, Christison, Rayer) maintain that the appearance of albumen in the urine of dropsical patients is the never-failing indication of organic mischief going on in the kidney, others (Wells, Cruickshank, Blackall, Graves) have insisted that this circumstance was often indicative of some febrile excitement of the circulating system, of some general or local inflammation, of functional derangement of the kidney at most, and sometimes not even of that, the albuminous impregnation of the urine being the mere effect of a general effusion of a serous fluid into all the cavities and interstices of the body. Mr. Cruickshank[10] in particular held albuminous urine to accompany 'every case of increased action of vessels, more particularly when this was of the inflammatory kind,' and believed that anasarca (which he calls *general dropsy*, and which he obviously considers as a disease dependent on increased vascular action) may be distinguished from the dropsy produced by a morbid condition of one or other viscera, from the circumstance of its always being accompanied by an albuminous state of the urine. Dr. Wells[11] concludes his truly excellent paper, 'On Dropsies that follow Scarlet Fever,' by advocating the practice of blood-letting in such cases, regarding them as connected with a *general inflammatory state of the system*, or, as I prefer to say, with the existence of internal inflammation. Dr. Blackall,[12] too, whose experience and candour deserve and secure our highest consideration, holds the presence of albumen in the urine of dropsical patients to be a certain indication of the existence of a general inflammatory diathesis or of some local inflammation which requires antiphlogistic measures—the abstraction of blood, low diet, &c.—for its subdual."
>
> "It is difficult[13] to resist such high authority; nevertheless, several distinguished practitioners have opposed themselves to the fundamental notion espoused by all the names that have just been mentioned (Bright, Gregory, Christison, Rayer). Dr. Graves,[14] for instance, positively denies that the albuminous state of the urine in dropsies always, or even generally, depends on structural changes in the kidneys. . . . The late Dr. McIntosh, of Edinburgh, and Dr. Elliotson have also expressed themselves against the notion of structural disease as the general cause of serous urine in dropsy of the cellular tissue. Legitimate deduction from my own experience in numerous cases of anasarca succeeding scarlet fever and exposure to cold . . . . would also lead me to conclude that this structural disease of the kidney could not have been the cause of the albuminous state of the urine which I found invariably to accompany the progress of the disease."

My excursions into the medical literature of the days when Richard Bright published his "Medical Reports," and of the years immediately following, have evoked a feeling of wonderment at the acumen and insight of physicians at the beginning of the nineteenth century; it was also interesting to find that there were physicians who were opposed to the deductions Bright had made, so that the heterodox opinions that I am about to offer you have not even the merit of being novelties. With Chaucer I must say :

> "For out of the old fieldes, as man saithe,
> Cometh al this new corn fro yere to yere;
> And out of old bookes, in good faithe,
> Cometh al this new science that men lere."
>
> *The Assembly of Fowles.*

Conclusions Based on Consideration of the Foregoing.

1. Uræmia is a complete misnomer based upon the erroneous opinion that the urine or renal excreta by retention from kidney disease cause uræmia.

2. The attempts to show that the signs and symptoms of Bright's disease are due to uræmia (*stricto sensu*) at least go to prove that the toxic symptoms met with in Bright's disease, in the minds of some workers of these times, *were* due to a poisonous state of the blood. To Bright and others dropsy and albuminuria in cases in whom the kidney was diseased were directly due to the kidney disease, and presumably so were all the numerous other signs and symptoms. To Willis and others quoted by him the source of the albuminuria and of the dropsy was not to be looked for in the kidney, but in the blood-stream—i.e., to some pre-renal source, e.g., in scarlet fever the albuminuria and dropsy were direct results of the changes in the blood produced by the scarlet fever. Presumably all the other toxic symptoms met with in scarlet fever may be looked for in the blood; indeed, there need be no hesitation whatever in believing that any infection can produce dropsy, albuminuria, and other toxic signs and symptoms, including the actual damage to the kidney itself.

3. It is therefore obvious that probably all cases of so-called primary disease of the kidney may owe all

met with in uræmia. I believe that when a case presents so-called uræmic manifestations, hyperpiesis is present, and if it is absent then at death cardiac hypertrophy will be found, showing that it had been present at one time or another. "Hyperpiesia" and "hyperpiesic," to my mind, are words preferable to "uræmia" and "uræmic": they do not commit us to an exclusive pathology, and as I have shown, I trust, are infinitely more accurately descriptive.

I have but one regret—I cannot describe the poisons circulating in the blood which produce hyperpiesis or any of the other symptoms of hyperpiesia; but I feel sure they are in the blood, and that they are in no way expressive of defective action of the kidneys. I must, in conclusion, add that I think many of the phenomena met with in the later stages of hyperpiesia, when symptoms of a so-called uræmic character develop, are much more likely to be due to toxins present in the blood as the result of some inflammation, somewhere in the body, than to metabolites present in the blood in excess owing to the default of the kidney whose duty it is to extrude such bodies.

SEROLOGICAL AND MORPHOLOGICAL CHARACTERISTICS OF THE PNEUMOCOCCUS:

AN ANALYSIS OF ORGANISMS ISOLATED FROM 77 CASES OF PNEUMOCOCCAL INFECTION.

BY A. L. URQUHART, *O.B.E.*, M.B., CH.B. EDIN., D.P.H.,
SENIOR ASSISTANT BACTERIOLOGIST, ST. THOMAS'S HOSPITAL;
GILLSON SCHOLAR IN PATHOLOGY OF THE SOCIETY OF APOTHECARIES, LONDON.

IN April, 1920, Sir Frederick Lister forwarded from the South African Institute for Medical Research some of his standard strains of pneumococci, with their homologous antisera, which he had isolated from cases of lobar pneumonia occurring in the mining area, in order that they might be compared with strains of pneumococci present in this country. In this communication comparison has been made with pneumococci isolated from cases of lobar pneumonia, and with those obtained from cases of pneumococcal infection other than lobar pneumonia. These results have also been correlated with those of the Rockefeller and other workers by means of Rockefeller anti-pneumococcal serums, so that it was possible to compare the results obtained with those of Lister and American workers.

The following list gives the relationship between the two nomenclatures:—

Lister's group.		Rockefeller type.
C	=	I.
B	=	II.
E	=	III.
A, D, F, G, H, J, K, X and unclassifiable	=	IV.

In some of the figures quoted below it will be seen that Type II. Rockefeller has been further subdivided, and Types IIa., IIb., and IIx. are noted which agglutinate slowly and incompletely with standard Type II. antiserum.

Isolation of Pneumococci from Pus and Sputum.

Pneumococci were obtained in pure culture from hæmocultures, but when sputum or pus was examined the organism was one of several present in the specimen, and although by looking at stained preparations of such material one could detect the typical capsulated pneumococci in large numbers, it was found to be very difficult in many cases to separate them from the other organisms present. For some time past Dudgeon's method (Wordley, 1921) has been employed, and has given most satisfactory results. Unglazed porcelain tiles 3 inches by 3 inches, sterilised by heat, were spread with the pus or sputum. The excess of moisture was rapidly taken up by the tile, and the resulting sticky mass was transferred to a second tile, spread out and left to dry to a flaky powder (1–3 hours). The powder was scraped from the tile, and a quantity spread on a blood-agar plate which was then incubated. By this means it was possible to get a plate on which the colonies were well separated, even although the original material contained many types of organisms. In specimens in which the types of organism are few, blood-agar slopes have been used in place of plates with satisfactory results. It is necessary to employ a glass screen mentioned by Wordley in his description of the method for the protection of the worker, as the powdered sputum is a dangerous source of infection, and in several instances contained tubercle bacillus.

Morphological and Cultural Characteristics.

The morphological and cultural characters of the pneumococcus noted in this paper have been examined. The typical appearance of the pneumococcus, a Gram-positive capsulated diplococcus pointed toward the free ends, and broader at the opposed surfaces, is best made out in fresh films of pus or sputum. It has been noted by many observers that these typical appearances may rapidly disappear on culture, and—by the loss of capsule formation, and the occurrence of chain formation, such as is frequently seen in cultures in liquid media—the pneumococcus may become indistinguishable from the streptococcus. In fluid cultures the pneumococcus forms a cloud throughout the medium, and on blood-agar the colonies are discoid and slightly granular. After 24 hours the colonies and the blood medium become brownish or greenish-brown, and this colour deepens with the age of the culture. Park and Williams (1905) have noted that this green colour is present in atypical colonies, and may be present in typical strains.

The cultural reactions of 77 strains of pneumococci have been noted on lactose, glucose, mannite, saccharose, starch, inulin, salicin, inosite, and litmus milk, the "sugar" media all containing 0·5 c.cm. of blood serum. The action on mannite, salicin, and inulin was variable, some strains producing acid, some having no action on the "sugars." Inosite was not fermented in any case. The remaining "sugars" and litmus milk were acidified in every instance. These strains of pneumococci were members of different serological groups, but no indication of grouping could be obtained from the fermentation reactions on the above-mentioned substances.

Twenty-eight strains of streptococci obtained from various sources have been tested in the same way, and in many instances similar reactions to those of the pneumococci were recorded. From these observations and those of Cole (1913), Dochez and Gillespie (1913), Logan (1921), and Cooper, Mishulow and Blanc (1921), all of whom have obtained somewhat similar results, one comes to the conclusion that as a means of classification of pneumococci the fermentation tests are of no value.

Results of Blood Culture in Pneumococcal Infections.

Blood cultures have been made in cases of pneumococcal infections during the pyrexial period, nutrient glucose-broth and distilled water being used as culture-media. White (1899), in giving results of blood cultures made in cases of pneumonia, quotes figures given by several workers. Stillman, examining 18 cases of pneumonia, obtained 6 positive cultures; in 2 of these the cocci were seen in blood films only, and did not grow in the culture-media. Of 12 cases in which negative blood cultures were obtained, 2 died; of 6 positive cases, 4 died. Kohn in 32 cases found the pneumococcus in the blood of 9 cases, of which 7 died and 2 recovered. Of 13 negative cases (including 2 cases dying of complications), 8 recovered, At a later date, he found that a considerable majority of the negative cases recover, whilst a similar proportion of the positive cases die. He concludes that the presence of the pneumococcus in the blood gives a very unfavourable prognosis. White found that of 19 cases of lobar pneumonia, all at least moderately severe, 10 were fatal. Thirty-two blood cultures were

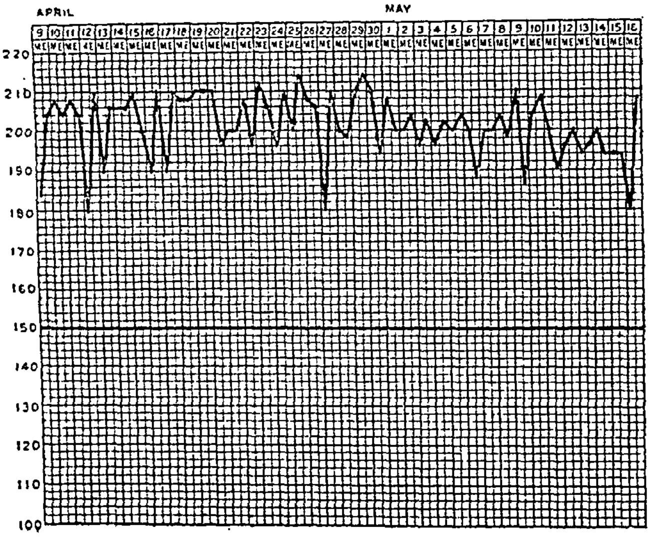
It seems therefore that the view revived by me as to the seat and origin of the poison causing the toxic signs and symptoms met with in so-called uræmia is more satisfactory than that developed immediately after Bright's discovery, and is not negatived by the definitions given by at any rate some contemporary authorities.

II. ILLUSTRATIVE CASES.

I now propose to give a brief account of four cases which have come under close observation, with results of post-mortem examinations, condition of the kidneys in each case, naked-eye and microscopically, as revealed by the post-mortem examination.

CASE A (*Fig.* 1).—*A single woman, aged* 50 years, cook by occupation. Three weeks previous to admission to hospital she had developed cough, shortness of breath, palpitation, and frequent vomiting. Her legs began to swell, and this led to her seeking relief. She had had two similar attacks two years and three months previously, respectively. She had had rheumatic fever. On admission she showed signs of mitral disease and cardiac failure—the pulse was irregular; the brachial artery was tortuous; the maximum impulse was diffuse and not forcible; the cardiac dullness to percussion was increased to the left and right; the aortic and pulmonary second sounds were accentuated; ascites, dropsy, and left pleural effusion were present; albuminuria was established on fourteen occasions, and absent on five other examinations: vomiting persisted, but was less frequent; the urine gradually became scanty. During her stay of 21 weeks in the hospital fever was noted only on four or five days; tachypnœa and paroxysmal tachycardia became very marked, and appeared to be relieved by removal of the pleural effusion, but returned again and were not relieved by a second removal of pleural effusion and drainage of the œdematous legs; shortness of breath was much increased, and cyanosis became a great feature; well-marked fits developed four days before death in one of them. The opinion of the physician in charge of this case was that she died from morbus cordis (mitral disease), associated with granular kidney, as shown by the presence of the mitral murmur, pleural effusion, albuminuria, and uræmia.

FIG. 1.



CASE A.—Part of a very full chart drawn up from five months' daily observations.

For permission to use the blocks from which the charts are printed I am indebted to the courtesy of The Oxford Medical Publications, who are preparing for publication my volume on Hyperpiesia.

CASE B.—A bricklayer, aged 45. While at work this man had fallen unconscious and was admitted to the hospital in this condition. On three former occasions he had had attacks of loss of consciousness and convulsions, 15 years, 4 years, and 5 weeks previously. His wife had had three miscarriages. When seen in the wards he was deeply comatose, although it was some hours since his loss of consciousness; his face was flushed and the breathing stertorous; the left arm and leg were flaccid; the supinator-, biceps-, knee- and ankle-jerks were present and equal; the abdominal reflexes were absent, and the plantar responses were extensor on both sides; he was incontinent of urine, and a catheter specimin showed a very small amount of albumin. The temperature was subnormal, and the pulse slow. There was no dropsy. Gradually the heart and respiration failed, and he died three to four hours after admission. The clinical diagnosis was hemiplegia from cerebral hæmorrhage into the right internal capsule.

You would probably have agreed with the clinical diagnosis made in these two cases, but probably you would have wondered what was the explanation of certain peculiar features in these two cases. There can be no doubt that the development of uræmic fits in the last few days of life of Case A would have excited much attention. You would have ransacked your memory to try and remember whether you had ever seen a case apparently of rheumatic mitral disease with cardiac failure resulting from muscular disease of the heart developing attacks of coma and convulsions. There was no escape from the conclusion that this woman died in a uræmic attack, and you would have been confident that the post-mortem examination would reveal one of the more or less familiar diseases of the kidney, especially if I had told you of a clinical feature which, for the purposes of this address, I have not yet mentioned. With regard to Case B, the diagnosis of cerebral hæmorrhage was comparatively easy, but you would have been in difficulties to find an explanation of the three previous attacks of coma and convulsions. A ready explanation for them would be that they were simply attacks of major epilepsy, and then realising that they had come on in middle life in a man whose wife had had three miscarriages you would have suspected that the cause of the epilepsy was some syphilitic disease of the cortex cerebri; but again I have suppressed a certain clinical feature, which encouraged the view that he had been suffering from kidney disease and the attacks were simply uræmic epilepsy.

Turning to the chief post-mortem discoveries in these two cases, it was found that:—

In Case A the heart weighed 20 oz., its chambers were dilated; the chamber walls were hypertrophied; there was mitral stenosis; the liver showed "nutmeg" change. The right kidney weighed 6 oz., and the left 7 oz.—the capsules stripped leaving a smooth surface, the substance was congested and not tougher than normal. Microscopically 1 per cent. of the Malpighian corpuscles were destroyed from past capsulitis, 96 per cent. of the corpuscles were normal except for congestion, the cortex was not reduced, there were small scattered areas of tubular atrophy and of fibrosis, many of the non-atrophied tubules showed cloudy swelling and epithelial degeneration.

In Case B the heart weighed 17½ oz.; the left ventricular wall was hypertrophied; there was a large hæmorrhage in the right internal capsule and no signs of cortical disease. The kidneys were of normal size and weighed 7½ oz. each; the capsule was not adherent; on stripping the capsule from the kidney the bared surface was smooth; the cortex was a little reduced. Microscopically 95 per cent. of the Malpighian corpuscles were normal, 5 per cent. atrophied, most of the tubules showed cloudy change in the epithelium as well as granular degeneration, a few tubules were atrophied, and there was some fibrosis.

Puzzling as the clinical accounts of these two cases are, the post-mortem findings are even more so. In both cases the weights of the heart were greatly increased; no doubt mitral disease contributed very largely to the increase in the heart weight in Case A, but why was the heart so much increased in weight in Case B? The idea that the heart may be hypertrophied from heavy manual work or athleticism has been abandoned, so that the occupation as a bricklayer cannot be looked upon as the cause of the increased weight of the heart. Again I must tell you that the clinical feature which I have suppressed in each of these two cases encouraged the view that in both of them, partly in Case A, and wholly in Case B,

In these tables it will be noted :—

(1) That the absence of hæmolytic activity of the pneumococci, when tested in a peptone-water medium containing 0·05 c.cm. of human red cells, has been observed in all but two instances: Table I., No. 132, and Table II., No. 107.

(2) That the lytic action of 2 per cent. sodium taurocholate in distilled water on the pneumococci has been observed in every instance, in two apparent exceptions: Table I., No. 132, and Table III., No. 126; lysis took place after these strains had been sub-cultured several times.

and possibly infarction of the kidneys accounted for the hæmaturia. The presence of casts and, towards the end, great reduction in urine, may suggest that possibly there was some serious disease of the kidneys of the nature of Bright's disease. Again I must tell you that I have suppressed the fact that another clinical sign was present, which I have satisfied myself is not a feature in cases of mitral valvular disease, or of degenerative disease of the heart muscle, both of which features appeared clinically to be present in Cases C and D.

I will now give the post-mortem findings of these two cases:—

In Case C the heart was found to weigh 17½ oz., the ventricular walls were hypertrophied; all the valves were free from disease; the coronary arteries were atheromatous but not occluded: the cardiac muscle was not fibrosed; the liver was "nutmeg," and there was fluid in one pleural cavity and in the peritoneum. The kidneys weighed 5¼ oz. each; the capsules were thick and adherent; the surfaces were finely granular; the cortex was not reduced. Microscopically 3 per cent. of the Malpighian corpuscles were destroyed, 97 per cent. were normal; there were small areas of tubular atrophy and fibrosis; the main bulk of the tubular epithelium was swollen and undergoing degeneration.

In Case D the heart weight was found to be 30 oz.; the ventricular walls were hypertrophied and the chambers dilated; there was no valvular disease; the liver was enlarged and showed a "nutmeg" appearance. Each kidney weighed 10 oz.; the capsule of each organ was thickened and adherent, and the surface laid bare was smooth. Microscopically it was found that about 5 per cent. of the Malpighian corpuscles were destroyed, 95 per cent. were normal; the cortices showed well-marked tracts of atrophy and fibrosis; the bulk of the tubules showed swollen epithelium or granular degeneration.

It is therefore clear that the diagnosis that these cases had died from valvular disease was quite wrong; the murmurs heard must have been simply due to dilatation of the chambers of the heart and of the valvular orifice concerned. As already admitted, defective action of the valves may have been responsible for the increased weight of the hearts in these two cases, but again I may remind you that each case revealed a clinical manifestation which I have not mentioned, which could explain the cardiac hypertrophy, and which some authorities think could explain how it was that the murmurs were heard. As to the kidneys, it will, I think, be agreed that there was little wrong with them, judged by the microscopical findings; and even accepting, for the moment, the prevailing view that uræmia is associated with grave kidney disease, the absence of uræmic symptoms in these cases would cause no surprise when the slight changes in the kidneys are observed.

III. DISCUSSION OF CASES.

The details of Cases A, B, C, and D must be kept in view as clearly as possible. A feature common to all four is the presence of a very large hypertrophied heart; but another feature almost as striking is that, despite the frequent occurrence of albuminuria, the kidneys in all four cases are practically normal. Tortuosity of the brachial artery was present when looked for. Now I disclose to you the fact that in each of these cases the blood pressure was raised, though only two observations were possible in Case B, each being 256 mm. The chart of Case A is part of a very full one, drawn up from five months' daily observations. The chart of Case C represents only a few days' observations, and the charts of Case D were drawn up as the result of two separate visits to the hospital. I think there can be no doubt that hyperpiesis was present in each of these four cases. My opinion is that these four cases represent what Sir Clifford Allbutt has described as hyperpiesia.[22] To use his own words, hyperpiesia "is a malady in which blood pressure rises excessively, a malady having a course of its own and deserving the name of a disease." I may add that it may be fatal, because cases C and D, though appearing to die of valvular and muscular disease of the heart, had no valvular disease, nor any other disease which could have proved fatal. The cause, I think, of their deaths was toxic in origin, and the end was brought about by the "defeat" of the heart, to use Sir Clifford Allbutt's own term, rather than by disease of that organ. I do not think that hyperpiesia is due to the gradual narrowing of the arteries of the body by any of the processes which masquerade under the name of arterio-sclerosis, and for a very simple reason. If you look at the first portion of the pressure chart of Case A you will see that in about a fortnight the pressure had become normal, and that about three weeks later it was higher than it ever had been. There was no discoverable intercurrent severe inflammation which could have caused the fall, and which, being recovered from, could have allowed the pressure to rise again. Nor can we imagine that arterio-sclerosis had departed in a fortnight, and during three weeks had again reached such a pitch as to make the blood pressure higher than before. It seems much simpler, therefore, to hypothecate a pressor toxin (or toxins) which, circulating in the blood, leads to contraction (but not to occlusion) of the arteries, with the result that the heart hypertrophies, and the strain induced by this interplay of heart and arteries causes the blood pressure to rise and the arteries to lengthen and become tortuous. There can be no reason to think that in these four cases the kidneys were in any way capable by chemical agency of causing the rise of blood pressure, because they were so little diseased, and because it has never been established that renin[23]—a pressor substance present in the kidneys—is responsible for physiological normal blood pressure, or for hyperpiesia. I do not know where this hypothetic toxic body (or bodies) originates, but I believe it is distributed by the blood-stream, and I believe it is pre- or extra-renal in origin.

I do not entirely agree with Sir Clifford Allbutt[24] because I believe that hyperpiesia in its later stages *may* reveal symptoms identical with those met with in certain well-known forms of kidney diseases—Case A was felt by the physician in charge to have died partly, if not entirely, from uræmia dependent upon granular kidney; but, as previously stated, the kidney was practically normal. Now I must confess that a large proportion of the cases of hyperpiesia which I have studied reveal granular kidney, or some other coarse form of kidney disease; but a very considerable number, though less, showed no more disease of the kidneys than I have related in the above four cases. Many of these latter cases—i.e., those who did not reveal kidney disease like Case A and Case B—revealed symptoms eminently uræmic, so I am prepared to go much further than Sir Clifford Allbutt, and to say that hyperpiesia may, in its more dangerous phases, exactly simulate the symptoms of various well-recognised forms of kidney disease, without the kidneys being diseased at all. The first part of my lecture aimed at showing that uræmia was due to poison (or poisons) circulating in the blood which was in no way referable to the faulty action of the kidneys, and I quoted Bright's contemporaries, some of whom firmly believed that albuminuria and dropsy, and presumably other symptoms and changes associated with them, even the kidney disease, were due to some general cause operating in the circulatory system.

CONCLUSION.

I have aimed at trying to show that in hyperpiesia we can find all the manifestations familiar to us in the past as uræmic. I have also tried to show you that hyperpiesia and uræmia—so-called—are due to the circulation of a blood poison (or poisons) which are not due to a fault of the kidney. It is common knowledge that the term uræmia is a misnomer, useful clinically, but unsupported by experimental investigation. Then, I maintain, the relationship of uræmia and hyperpiesia is easily settled. Hyperpiesia reveals in its advanced stages each and every manifestation incidence of cases of serious pneumococcal infections as lobar pneumonia, broncho-pneumonia, meningitis, and septicæmia occurring in the A, B, and C infections, 35, or 72 per cent., fall into this category, the remaining infections being of a milder type—bronchitis, cold, asthma, &c. Lister's figures (1917), noted above, place some 70 per cent. of his cases of lobar pneumonia in Types A, B, C, and E, and Cole (1913) places some 70 per cent. of his pneumonia cases in Types I., II., and III. The figures for the three areas would appear therefore to be somewhat similar, Types I. and II. pneumococci being frequently present in serious pneumococcal infections in this country. On an examination of the Type IV. infections, 12, or 40 per cent., are of a serious nature and 60 per cent. more mild. Thus, although over half the cases from which this type of coccus was isolated are mild, these cocci are capable of producing any of the serious forms of infection, meningitis, lobar pneumonia, and broncho-pneumonia—instances having appeared in the list of cases examined above—but do not produce these serious forms of infection in such a high percentage as the Types I. and II. pneumococci.

Conclusions.

1. That from the laboratory methods employed the pneumococcus presents its most typical appearance in fresh body exudates, and that bile solubility and the absence of hæmolytic activity are almost constant characteristics of the pneumococcus.
2. That for the separation of pneumococci in sputum and pus, Dudgeon's method is a convenient and satisfactory one.
3. That the fermentation reactions of the pneumococcus are of no value for the division of the organisms into types.
4. That pneumococcal antibodies corresponding to the type of pneumococcus responsible for the infection, though not present in the early stages of the disease, are usually formed in the post-critical blood serum of cases of lobar pneumonia, and in the later stages of some other pneumococcal infections.
5. That the pneumococci responsible for lobar pneumonia and other serious pneumococcal infections in this country are similar to those found in America and South Africa.
6. That Type IV. pneumococci are capable of producing any of the serious infections due more commonly to Types I. and II. infections.

I have to thank Sir Frederick Lister for his kindness in forwarding the standard strains of pneumococci which formed the basis of this work. I am also greatly indebted to Prof. L. S. Dudgeon for much kindly help and advice, and to the members of the staff of St. Thomas's Hospital for permission to obtain material from their cases, and for the use of their clinical notes.

THE IMPORTANCE OF THORACIC RESPIRATION.

BY SIR W. ARBUTHNOT LANE, BART., M.S. LOND., F.R.C.S. ENG.,
CONSULTING SURGEON, GUY'S HOSPITAL, ETC.

MY object in writing this paper is to call attention to the very important part played by thoracic respiration at all periods of life; to the necessity of observing its extent; to the recognition of the factors that affect it prejudicially; and to the consideration of the best mode of dealing with it and with the conditions which impair its efficiency.

When I was working at the changes which the skeleton and soft parts of the labourer undergo in consequence of an arduous occupation my attention *was called to the function of the intercostal muscles*, the share they take in the respiratory process, and the modifications they undergo in the various types of workmen. At that time the mechanics of the respiratory process were, like all the mechanics of the skeleton, described in a most crude and superficial manner. The action of the intercostal muscles was illustrated in the text-books of physiology by a *vertical rigid rod representing the spinal column*, and attached to this rod by hinges were parallel bars representing the ribs, and to these bars pins were fixed at intervals. The supposed action of the internal and external intercostal muscles was demonstrated by attaching to these pins elastic bands having the direction of the fibres of these muscles. As a result of this representation it was stated that the external intercostal muscles raised the ribs, and were consequently inspiratory muscles, while the internal intercostal muscles depressed the ribs and were expiratory in their action.

Free Movement of Vertebral Segments.

The fallacy in this experiment lies in the fact that far from being a rigid body the vertebral segments which make up the dorsal spine move very freely on one another around a transverse axis in an antero-posterior vertical plane. Indeed, on observing an individual passing from extreme inspiration to extreme expiration the alteration in the curve of the spinal column is a more marked feature than the elevation and depression of the costal arches. The vertebræ, instead of forming a rigid rod, are freely mobile in an antero-posterior plane. The sternum affords the fixed bar, while the elasticity of the costal cartilages permits of its depression and elevation. This is demonstrated by a change that takes place in the first costal cartilage of the labourer under the influence of great pressure. In consequence of this strain a process of ossification commences in the periphery of each extremity of the first costal cartilage, and gradually extends till the whole cartilage has been converted into bone. *To meet the flexion* of the spine and the consequent movement of the vertebræ in an antero-posterior plane a new joint develops in the ossifying cartilage. This is at first *purely amphiarthrodial in type, but when fully* developed it forms an arthrodial joint which allows of very free movement between the segments of the ossified cartilage, one of which is continuous with, and inseparable anatomically from, the first rib, and the other forms a part of the manubrium.[1] Figs. 1, 2, 3, and 4 represent several of the stages in the development of this joint.

Curiously enough, the physiologist makes no mention of the very obvious movement of the vertebræ in an antero-posterior plane. I have looked up the mechanics of respiration in an excellent text-book of physiology,[2] and find that the same diagrams are still employed to illustrate them, and that "the made, and in 3 cases the pneumococcus was found in life. In 2 of these positive cases general pneumococcal infection was found post mortem. In 8 cases with negative blood cultures, although the pneumococcus was present in the lungs, no evidence of a general pneumococcal infection was found post mortem.

---

[1] Some points in the physiology and pathology of the changes produced by pressure in the bony skeleton of the trunk and shoulder-girdle, Guy's Hospital Reports, 1886.

[2] Starling: Elements of Human Physiology.

Thirty-four blood cultures were made during this work, and of these 19 were positive and 15 negative. The pneumococci have been typed and are distributed as shown in Table A.

TABLE A.

Rockefeller Nomenclature.	Lister's Nomenclature.	Number of blood cultures.	Positive.	Negative.
—	Group A	2	1	1
Type I.	C	20	8	12
,, II.	,, B	7	5	2
,, IV.	Unclassified.	5	5	0

In Lister's Group A 2 patients were examined by blood culture: one, a case of lobar pneumonia with empyema (positive), died; the other, a case of broncho-pneumonia (negative), recovered.

In Type I. the 8 positive results were obtained in 5 cases of lobar pneumonia, 2 of meningitis, and 1 of septicæmia. The negative cultures occurred in 10 cases of lobar pneumonia, 1 of broncho-pneumonia, and 1 of chronic empyema. Of these 8 positive blood-culture cases 5 died, 2 of lobar pneumonia, 2 of meningitis, and 1 of pneumococcal septicæmia. Of the 12 cases in which negative blood cultures resulted 2 died, one of lobar pneumonia, and the other of a chronic empyema associated with advanced waxy disease.

In Type II. the 5 positive blood cultures were all obtained from cases of lobar pneumonia, while 1 lobar and 1 broncho-pneumonia gave negative results. Of the 5 positive cases, 2 died; both negative cases recovered.

In Type IV. 5 positive cultures were obtained, 3 from cases of lobar pneumonia, and 2 from pneumococcal meningitis. Both meningitis cases and 1 of the pneumonia cases died.

In all cases, in which a positive culture was obtained, the examination was made within seven days of the onset of the disease, and it is noted that of the 4 cases of meningitis examined all had positive blood cultures and all died. In the cases where a negative culture resulted, 7 were made during the first week of illness, 4 during the second week, 1 during the third, 2 during the fifth, and 1 from a chronic empyema established for seven years in which a pyrexial condition was present. In those cases of pneumonia with pyrexia during the third and fifth weeks an empyema was present.

From an examination of these results it will be seen that of 19 positive blood cultures death resulted in 11 cases, whereas in 15 cases where a negative blood culture was obtained, 2 died; one a case of lobar pneumonia which died on the eighth day, the other a case of chronic empyema with advanced waxy disease. Although the number of cases examined by blood culture is small, it would appear that in cases of pneumococcal infections a positive blood culture is of grave significance.

Formation of Specific Agglutinins and Opsonins in the Blood Serum of Persons Suffering from Pneumococcal Infections.

Lister (1913) pointed out that the serums of patients recovering from lobar pneumonia usually acquire opsonins and agglutinins for the particular strain of pneumococcus responsible for the infection, and that "virulent" pneumococci—i.e., pneumococci directly derived from a hepatised lung—are readily phagocyted and agglutinated by such serums. These antibodies are not found in the early stages of the infection, but appear at or about the time of the crisis, and continue in the blood for some time after [illegible] period. The blood serums from the pre-critical stage of 18 cases of lobar pneumonia, 2 from early broncho-pneumonia, 5 from pneumococcal meningitis, 1 from bronchitis, 1 from a pneumococcal septicæmia, and 2 from cold in the nose—29 in all—have been tested against type strains or strains obtained from the cases, in no instance was any evidence of agglutination or phagocytosis of the pneumococci noted. Similarly 41 serums taken after the crisis in cases of lobar pneumonia, or at a late stage of other infections, have been examined for the presence of opsonins and agglutinins. Table B shows the results obtained.

TABLE B.

Nature of infection.	Positive.	Negative.
Lobar pneumonia	24	1*
Broncho-pneumonia	6	3
Chronic empyema	2	0
Bronchitis	0	3
Septicæmia (pneumococcal) ..	0	1*
Cold in head	0	1

* Subsequently died.

These findings are in agreement with those of Lister as regards the lobar pneumonia cases, but cases of broncho-pneumonia and chronic empyema also appear to produce antibodies in the serum. These antibodies may be used to determine the type of pneumococcus which has caused the infection and may serve as a useful guide to vaccine therapy. In the following Tables I., II., III., and IV. are noted the cases from which these observations have been made. The technique of the agglutination method used during this work is similar to that used by Sir F. S. Lister (1913), who modified Sir A. Wright's opsonic-index method for this purpose. Thick dehæmoglobinised blood films have been used for the observation of agglutination and phagocytosis of the cocci in preference to the usual blood films, as by this means the clumps of pneumococci are not submitted to the action of the spreader.

Serological Reactions of 77 Strains of Pneumococci Isolated from Various Sources.

In the following tables are set out the chief particulars of the pneumococci isolated during this work in their serological groups. Where agglutinins and opsonins were developed in the blood serum of the cases examined, strains of cocci derived from two separate sources where possible—such as blood culture and empyema pus—were tested with this serum and with standard anti-pneumococcal serum. Thus in Table I., No. 43, strains of cocci, obtained from the sputum and from empyema pus, agglutinated with anti-pneumococcal serum Type I., and with the post-critical serum of the case, phagocytosis of the cocci being present. In Case 71, Table I., a case of meningitis, death took place; the blood serum contained no agglutinins, both strains isolated from the cerebro-spinal fluid and from the blood culture agglutinated with Type I. antiserum. In no case have two "standard" strain pneumococci (and by this I understand Types I., II., and III.) been isolated from any single patient, nor have agglutinins or opsonins for more than one strain of pneumococci been found in the post-critical serum of any case.

Pneumococcus C Lister, or Type I. Rockefeller.

In Table I. are set out the "C" Lister or Type I. group of pneumococci. This group contains 31 members, of which 26 were obtained from cases of lobar or broncho-pneumonia, and it is noted that 11 of these cases were complicated by empyema formation. Of these 31 cases eight died, four of pneumonia, one complicated by a terminal meningitis (No. 173, a chronic empyema of seven years' standing, who was in a state of advanced waxy disease on admission to hospital for operative treatment), one of meningitis, and one of septicæmia (No. 182).

Case No. 182 is of interest, as chronic lymphatic leukæmia had been present for some two years prior to the terminal infection. This patient was infected with what appeared to be an influenzal cold, but his condition became serious. There were fleeting signs of pneumonic consolidation in the lungs, but no definite areas could be located. Positive blood cultures, in which enormous numbers of pneumococci were found after 12 hours' incubation, were obtained on four separate occasions during the 14 days of acute illness. Thus in this case a pneumococcal septicæmia persisted for moreover, all objective evidence of adenoid growth had disappeared. Such an improvement could not have been effected without constant care and attention on the part of the highly trained nurse who carried out the treatment.

In 1896[4] and subsequently I published several papers on the importance of improving the respiratory capacity of feeble children, and particularly those who were the subjects of adenoid hypertrophy with or without operation, and to my surprise my suggestions met with violent opposition. Sir Felix Semon, the then recognised authority on laryngology, devoted three and a half columns of a lecture, which was published in the *British Medical Journal*,[5] to show that my views on the supposed benefits to be derived from respiratory exercises were ridiculous. To give an idea of the antagonism that the employment of breathing exercises aroused, I quote a few lines from the lecture of this distinguished surgeon. "Well, gentlemen, I may be an incurable sceptic, but I have no hesitation in telling you that I do not believe for a moment that a single child which has got well-marked adenoids has been, or ever will be, cured by breathing exercises, all reports to the contrary notwithstanding. I mean no disrespect to Mr. Arbuthnot Lane, but I cannot help saying the whole idea seems to me preposterous"; and again: "If it should be called unscientific to say plainly that the rationale of his treatment was a mystery to them, I, for one, must plead guilty to the soft impeachment. How a genuine lymphoid hypertrophy can ever be expected to be dispersed by breathing exercises completely passes my understanding."

It would be interesting to compare the views Sir Felix Semon then enunciated on the value of respiratory exercises with those now held by laryngologists, by medical men generally, and even by school teachers and the better educated part of the public. It was not till later that I realised the important influence that intestinal auto-intoxication and chronic intestinal stasis exert upon the respiratory and other functions of the body and how far they are responsible for the development of diseases.

In 1902 I opened a discussion[6] on the subject at a meeting of the British Medical Association in Manchester, when there was much difference of opinion, though the ideas which were expressed by the several speakers, notably by Dr. Harry Campbell, showed that a change of view was taking place with regard to the mechanics and affections of the nasopharynx.

Stasis as the Chief Cause of Lowered Vitality.

Intestinal stasis develops at an early period in the lifetime of the child. While the infant wears napkins it passes its motion when the bowel recognises the desire to evacuate it. When the napkin is discarded the child is taught to retain the products of 24 hours' digestion in the large bowel, with the result that the pelvic colon elongates and secondary changes ensue. Sooner or later the contents of the small intestine become infected by organisms and the food-supply is contaminated. This results in a poisoning of all the tissues and organs of the body, rendering them unable to perform their functions in a normal manner and reducing their capacity to resist the inroad of micro-organisms. The observation of a large number of delicate children shows that in them thoracic respiration is in abeyance, and that a tape encircling the chest undergoes no variation whatever during respiration. The tissue in the infant in which the earliest evidence of infection by organisms is observed is the lymphoid tissue in the naso-pharynx. Later in life the evidences of lowered resisting power are shown in an infection of the periodontal membrane to which the name of pyorrhœa has been given. Both these conditions, which are secondary to stasis, are regarded by many as diseases appearing spontaneously and being themselves causes of stasis and its results. As age advances the amount of energy which can be expended in effecting thoracic respiration diminishes, and the chest and dorsal spine assume the curves that one associates with that time of life. Perhaps most of this is due to the fact that stasis increases with age, and that it is the prime factor in producing disease and death. Again, a great deal of defective thoracic respiration is due to habit, the individual neglecting to keep his chest working efficiently. Besides being very deforming it serves to diminish the oxygenation of the blood and to hasten degenerative processes throughout the body.

A recognition of the facts to which I have called attention in this paper must impress the reader with the importance to the individual of keeping the function of thoracic respiration in an efficient condition, even though little consideration is given to the state of the muscular system generally; also that chronic intestinal stasis, that dread accompaniment of civilisation, should be met by every possible means if the tissues of the body are to be kept in the best possible condition.

THE RATIONALE OF THE WASSERMANN REACTION.

An Abridged Account of a Paper Read Before the Dermatological Section of the Royal Society of Medicine on Oct. 20th, 1921,

BY J. E. R. McDONAGH, F.R.C.S. ENG.,
SURGEON, LONDON LOCK HOSPITAL.

THOUGH the Wassermann reaction (W.R.) has been extensively employed since 1907, it cannot be said that much progress has been made in unravelling its *modus operandi*. Some have laid great stress upon the possible interpretations of a positive and negative reaction, but those with a large clinical experience are coming to the conclusion, that a negative reaction signifies nothing, and that a positive reaction means no more than that the patient has had syphilis. It is now being recognised that the reaction can be used, neither as a regulator of treatment nor as a test of cure, and that a positive reaction does not necessarily signify that the disease is active and that the patient requires treatment. Though the experimental work about to be described will form sufficient proof of the statements just enunciated, the main object of this paper is to detail as far as is possible the changes undergone by the protein particles in syphilis, and to throw more light on certain problems which so far have remained unsolved. Before doing this it will be necessary to consider the hæmolytic system, the foundation of all complement-fixation tests, and to point out the relationship it bears to the first part of the W.R.

Hæmolytic System.

An immune serum plus complement will cause red blood corpuscles to give up their hæmoglobin, and

11 days. Five days before death melæna was present, and the last culture, taken two days before death, contained not only the pneumococcus in large numbers, but also streptococci and the paratyphoid "C" bacillus. At no period of the septicæmia were agglutinins or opsonins found in the blood serum. Unfortunately no post-mortem examination could be made.

Case No. 132 was that of a child of 5 months, who was seen suffering from a membranous condition of both conjunctivæ. A Type I. pneumococcus was isolated; the child became blind.

Of the 31 cases of C or Type I. infection it is noted that 26 were isolated from cases of severe illness, and that five were obtained from mild infection, two of common cold, two of bronchitis, and one of asthma.

Pneumococcus B. Lister, or Type II. Rockefeller.

In Table II. are set out the particulars of the 11 cases forming this group. Eight of these cases are lobar pneumonia, 1 broncho-pneumonia, 1 pleurisy, and 1 asthma. Two cases, both of lobar pneumonia, died. None of these cases developed empyemata. The only cases of familial infection by the pneumococcus which have been encountered in the course of these investigations occurred in this group.

Three cases (Nos. 73, 74, and 78, Table II.) were all living in the same house, and all were admitted to hospital within seven days suffering from acute lobar pneumonia. No. 73, the father, aged 47, was admitted on the second day of illness. The left base was consolidated, and later the whole left lung became involved. Blood culture made upon the third day of the illness contained Type II. pneumococci in large numbers. Crisis occurred on the eighth day, but the post-critical serum contained no agglutinins or opsonins. Death took place on the ninth day from cardiac failure. At the post-mortem the left lung was in a state of grey hepatisation. The right lung was very congested, and in parts almost solid. No. 74, son of No. 73, aged 17, was admitted on the first day of illness suffering from hæmoptysis and pain in the left chest. Consolidation of the left base was present. The temperature fell by lysis on the seventh, eighth, and ninth days. Convalescence was normal. Blood culture made on the second day contained numerous pneumococci Type II., and a Type II. pneumococcus was isolated from the sputum. The post-critical serum contained both opsonins and agglutinins for Type II. pneumococcus.

No. 78, a son of No. 73, was admitted to hospital on the first day of illness. The right base was consolidated, the left base congested. The temperature fell by crisis on the seventh day, and convalescence was normal. This patient was not investigated until the eleventh day, when the temperature was normal. From the sputum a Type II. pneumococcus was isolated, and his post-critical serum contained agglutinins and opsonins for the Type II. pneumococcus.

These three cases serve to illustrate the occasional occurrence of a small epidemic of lobar pneumonia. Case No. 119, Table II., presented the clinical signs of pleurisy, and although rusty sputum was expectorated in considerable quantity, no consolidation of the lung was located. A Type II. pneumococcus was isolated from the sputum. A Type II. pneumococcus was isolated from one case of mild infection, No. 107, the remaining 10 cases were severely ill.

Pneumococcus A Lister, Type IV. Rockefeller.

In Table IIa. are set out the five strains of Lister's A pneumococcus, which have been isolated during this work. As noted above, Lister (1917) states that 31 per cent. of the pneumococci isolated by him have belonged to this group, 21·6 per cent. to the C group, or Type I. Rockefeller, and 16·2 per cent. to his B group, or Rockefeller Type II. Strains of this Type A pneumococcus were sent to the Rockefeller Institute, examined by Dochez and Gillespie (Lister 1913), and placed in Type IV. This strain has apparently not been found in America. In examination of the serological characteristics of these Type A pneumococci by the opsonic technique with 15 minutes' incubation, no agglutination or phagocytosis of the cocci occurred, but when the incubation time was increased to one hour some small but definite degree of reaction was noted and these A pneumococci have been placed in this communication as a sub-group of Type II. for this reason. Two cases of lobar pneumonia, both of which were complicated by empyema, and two cases of broncho-pneumonia were infected by this A pneumococcus, and in all four cases agglutinins and opsonins were present in the blood serum. In the fifth case, No. 118, Table IIa., a malignant growth of the lung was present; an empyema developed, from which this A pneumococcus was isolated. This case died, but no antibodies were found in the blood serum.

This Type A pneumococcus, so frequently observed in the natives of South Africa, is therefore present as a pathogenic organism in this country, though it has not yet been definitely identified by workers in America. Of the 5 cases due to this type of infection, 3 died, the causes of death being lobar pneumonia, broncho-pneumonia, and empyema complicating malignant disease of the lung. As far as one can judge from this small series of cases the presence of the Type A pneumococcus is associated with a severe type of infection.

Pneumococcus Unclassified Lister, Type IV. Rockefeller.

Thirty strains of pneumococci have been isolated which do not correspond to Lister's F, G, J, or K strains, and must therefore be placed in his unclassified list—that is, the Rockefeller Type IV. From these 30 strains 4 have been taken and antiserums (designated Harding, Hinman, Eccles, and 5073) prepared. Pneumococci Harding and 5073 were isolated from 2 cases of meningitis; Hinman and Eccles were obtained from the sputum of cases of chronic bronchitis. With these 4 antiserums it was possible to group 14 of the 30 Type IV. pneumococci. In Table III. are set out the particulars of these sub-groups Harding, Hinman, and 5073.

Sub-group Harding: Eight Cases.—No. 84, Table III., was the standard strain of this group, and was obtained from the blood stream and cerebro-spinal fluid of this case of meningitis before death. Seven further strains of this sub-group have been identified, two from cases of lobar pneumonia, four from bronchitic sputums, and one from common cold. Two cases—the original meningitis case, and one case of lobar pneumonia—died.

Sub-group Hinman: Three Cases.—No. 130, Table III., was the standard strain of this small group, and was isolated from the sputum of a case of tuberculous broncho-pneumonia. The sputum contained numerous tubercle bacilli. The remaining two strains were isolated, one from the sputum of a case of chronic bronchitis, the other from a case of post-anæsthetic broncho-pneumonia, who subsequently died. This case, No. 174, developed an empyema.

Sub-group 5073: Two Cases.—The standard strain, No. 126, Table III., was obtained from the cerebro-spinal fluid of a boy who fell from a bicycle, fractured his skull, and developed a pneumococcal meningitis. In this case the pneumococcus failed to lyse in 2 per cent. bile-salt until sub-cultured several times. The second example of this sub-group was isolated from the pus of an empyema.

Sub-group Eccles: One Case.—This organism was isolated from the sputum of a case of chronic bronchitis, and so far no further examples of this sub-group have been isolated.

Unclassified Pneumococci Type IV. Rockefeller.

In Table IV. the remaining 16 strains of pneumococci are set out, which were not grouped by any of the anti-pneumococcal serums used during this work. One case, No. 120, Table IV., a child of 4 months was admitted to hospital with an abscess on the back of the hand which had been present for six days. The child had a high temperature, and had developed signs of meningitis. The cerebro-spinal fluid contained pus and pneumococci, and the blood culture was positive, enormous numbers of cocci being present in a 12-hour culture. A thick blood film contained several groups of pneumococci. The child died 10 days after the abscess of the hand developed, but no antibodies were present in the blood serum. This was the only death amongst the 16 cases in this group. Four cases of lobar pneumonia, 2 of which developed empyema, 1 of broncho-pneumonia, 6 of bronchitis, and 4 of common cold are present in this collection of unclassified pneumococci.

From a survey of these serological groups of pneumococci one finds that of the 77 cases examined 47 are members of Lister's A, B, or C groups—i.e., Types I. and II. Rockefeller, with the addition of the A group; and 30 cases belong to the heterogeneous collection Type IV., none of which were found to be similar to Lister's F, G, J, or K groups. Taking the to which protein belongs, but it is a forced and not a spontaneous process.

On the other hand, a non-metal, acting as a condenser, at first diminishes the electronic activity of the protein particles, no electrons being discharged. When a lethal dose and several small doses are prescribed, the conservation of electrons, with the resulting increase of hydrogen on the surface, cause the particles to increase their "baseness." Such a step leads to an increased avidity for electrons, which the complement added cannot satisfy, consequently a positive C.F.T. is obtained. If my reasoning is correct the injection of a non-metal or condenser should return a positive reaction produced by a metal or conductor to a negative reaction, and cause the serum to give an ultra-microscopic picture indistinguishable from the normal. Not only is this what happens but the converse is also true. Though the reaction may be reduced to negative if previously positive, or to positive if previously negative, when a single injection of a metal is administered after several injections of a non-metal and vice versâ the ultra-microscopic pictures remain unaltered. This is likewise the case in late syphilis, and shows that once the particles have been accustomed, so to speak, to accommodate themselves to the altered conditions, they continue to perpetuate the changes, irrespective of the drugs prescribed. Consequently one cannot surmise from a given reaction in syphilis how the causative organism is behaving.

Effect of Metals and Non-Metals on Syphilitic Serums.

In early syphilis metals first increase the positivity of the C.F.T. because the initial stage of dispersion is accompanied by marked electronic activity. In the late stage of dispersion the reaction becomes negative, and occasionally the injection of a non-metal will re-convert it into a positive. Non-metals alone cause an immediate diminution of the positivity with an aggravation of the clinical signs, but their continued administration leads to a degree of positive reaction, which can be reduced only by the employment of metals. In late syphilis, if the reaction is negative to start with, a non-metal acts as a better provocateur of a positive reaction than a metal. If positive to start with, a non-metal will render the C.F.T. temporarily negative quicker than will a metal.

Changes Undergone by the Serum in Syphilis.

The protein particles undergo three main changes: (1) increase in number; (2) surface change; (3) mass change.

Increase in Number.—This change is most noticeable in early syphilis and can be detected before the C.F.T. is positive, but any manœuvre which sets in motion the spontaneous process of condensation will cause the same to give a positive reaction. This can be achieved by shaking with insoluble substances, such as barium sulphate, tin oxide, bismuth subnitrate, &c. Occasionally in late syphilis an increase in number is to be observed, but in such cases the C.F.T. is always negative and does not change into positive on the administration of a non-metal. These particles are albumin particles which always nullify, if in sufficient quantity, a positive reaction given by globulin particles. They are caused by a conversion of lipoid-globulin into albumin, and all the cases I have investigated had a marked degree of hyperpiesis. Whether the hypertension is due primarily to the increased viscosity of the serum or to the reduction in the surface electrification of the protein particles I cannot at present determine. I am strongly of the opinion that the changes in the vessel walls and kidneys are secondary to those in the serum.

Surface Change.—The protein particles in syphilis contain more electrolytes than normal; they are therefore capable of greater electronic activity. The discharge of electrons—i.e., the oxidising action of the particles—in the form of electricity and heat to overcome the parasites results in a condensation of the particles and in an increase of their "baseness."

As the disease advances and the electronic activity is continued, the particles lose many of their surface electrolytes. This increases their power of adsorption, which in vitro is measured by precipitation; consequently the most positive serums are usually late syphilitic serums. This being the fact at the stage when there are fewer organisms, again supports the view expressed that there is no parallel between the two. When the loss of electrolytes is exactly counterbalanced by the mass change, the lipoid-globulin so formed reaches its iso-electric point. At this point protein is, so to speak, dead and is excreted into the urine and into the general peritoneal cavity. This protein when collected invariably gives a negative C.F.T. Electronic activity resulting in condensation and increase of "baseness" imparts to particles so altered the chemical and physical properties of globulin. A continuation of the same leads to the formation of lipoid-globulin, which in its turn may be converted into albumin. The changes through which protein can pass are likewise cyclical in nature: Albumin —> globulin —> lipoid-globulin —> albumin.

Mass Change.—Apart from changes already observed, the mass exhibits an increase of amino-groups in early syphilis and an increase of lipoid material in late syphilis. The former is proved by Van Slykes's estimation of amino-nitrogen, and the latter is suggested by the behaviour of certain compounds on normal protein particles, by ultra-microscopic examinations, and by the effect produced on serums by the passage of electric currents. Lipoid-globulin can be formed at the negative pole and by shaking a serum with α-naphthylamine. Sometimes ringed particles are formed which in turn, on continued passage of the current, become converted into sheaf-shaped crystalloid bodies, which at present I take to be the glyceryl-esters of the higher fatty acids. Summed up the position is as follows:—

When the increase of electrolytes bears the same ratio to the amino-groups as occurs normally, the C.F.T. is negative. When the electrolytes become dissipated and the protein mass has to undergo changes to compensate for the loss, the C.F.T. is positive, because the adsorptive capacity of the particles is increased with the hope of being able to take from the particles added the electrolytes necessary to restore the balance. When the loss of electrolytes is just balanced by the substantive changes the C.F.T. is negative. When the electrolytes are still further destroyed, the C.F.T. is anti-complementary, because nothing added can restore the balance; in fact, anything added only furthers the precipitation. This stage corresponds to that produced when a normal organ is extracted with alcohol or acetone.

Thus we are now able to visualise the exact action of antigen. In fact, certain protein particles when rendered anti-complementary will serve as the antigen. A W.R. can actually be undertaken with ingredients made from the patient's own blood with the sole addition of some colloidal silicic acid for use as the amboceptor. A serum can be rendered anti-complementary by shaking with naphthalene, α-naphthol, and α-naphthylamine. If the serum is filtered, dried, and dissolved in saline, only the one treated with α-naphthylamine will act as antigen. α-Naphthylamine converts the protein particles into lipoid-globulin, diminishes the surface-tension, and diminishes the viscosity of the liquid medium. Further, it causes marked agglomeration and condensation of the protein particles. In other words, it imparts to the protein particles those characters upon which we have seen the C.F.T. depends. A like degree of agglomeration and condensation occurs normally in the serum of most pregnant women. This explains why at least 10 per cent. of non-syphilitic women when they are pregnant give a positive C.F.T., and why many syphilitic women (except those recently infected) give a negative C.F.T. From the foregoing we can also understand why repeated freezing and thawing, exposure to alterations of atmospheric pressure and to radio-active bodies, and shaking with various non-electrolytic substances, tend to make a normal serum give a positive or anti-complementary reaction. They make a slightly positive serum more positive external intercostal muscles, which shorten and so raise the ribs," are regarded as inspiratory muscles, and that "the internal intercostals depress the ribs and act as expiratory muscles." I would point out that the direction of the fibres of the external intercostals is continuous with that of the external abdominal oblique, a powerful muscle of expiration and a flexor of the thorax, dorsal and lumbar spine, while the reverse is true of the internal abdominal oblique, whose fibres continue the direction of the internal intercostals.

My observations on the anatomy of the labourer showed beyond a shadow of doubt in my mind that the internal intercostal muscles are the most powerful extensors of the dorsal spine, and are the chief muscles of thoracic inspiration. Their function is to extend the bodies of the several vertebræ upon one another, and to raise the ribs and sternum correspondingly. I also demonstrated that the external intercostals are the most powerful flexors of the dorsal spine, flexing the dorsal vertebræ upon one another and depressing the costal arches and sternum correspondingly. In extreme inspiration the dorsal spine is extended to its utmost, while in extreme expiration it occupies a position of extreme flexion. The normal respiratory effort moves within a varying degree between these extreme limits.

Showing Four Stages in Joint Development.

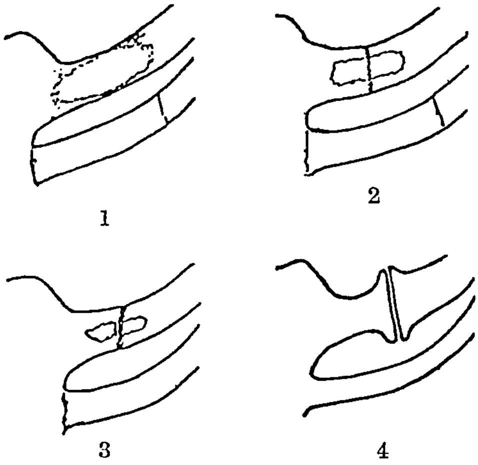

FIG. 1 shows the gradual formation of bone in the periphery of the extremities of the first costal cartilage.

FIG. 2 shows an extension of this process and a transverse marking in the bony sheath and residual core of cartilage, where the cells have arranged themselves at right angles to the long axis of the cartilage, and have elongated and formed fibrous tissue.

FIG. 3 shows a more advanced stage, the fibrillation having extended through the whole breadth of the cartilage, forming an amphiarthrodial joint.

FIG. 4 shows the fully developed arthrodial joint, the opposing surfaces of which exceed in area that of the normal cartilage.

The "Intercostal Ligament."

In such a labourer as the coal-heaver, who carries loads on his back, the constant strain on the internal intercostal muscles in opposing the forward displacement of the upper dorsal vertebræ—more especially the first and second—results in the formation of a very dense layer of ligamentous material which lies internal to the internal intercostals and continues the direction of its fibres. It extends from the posterior three-fourths of the first rib downwards and backwards through the subjacent spaces in a continuous plane to the spine. It is clearly a retrocession of the deeper part of the internal intercostal muscle, and it serves to diminish the expenditure of energy by this muscle. As I had seen no reference to this structure in works on anatomy I called it "the intercostal ligament." It affords an excellent example of labour economy, while at the same time it demonstrates the action of both internal and external intercostal muscles. This ligament and the mode of development of the joint in the ossifying first costal cartilage are fully described in the paper in the Guy's Hospital Reports for 1886. It is quite clear that diaphragmatic—or, as it is commonly called, abdominal—respiration is a more perfect reflex than is thoracic respiration. This is due to the fact that the action of the diaphragm is essential to life and makes no apparent demand upon the energy of the individual. The increase in the capacity of the chest, which is effected chiefly by the action of the internal intercostal muscles and the consequent change of posture of the individual, involve an expenditure of energy which is proportionate to the extent of the effort. Any condition that lowers the vitality of the individual, or which, in other words, reduces the capacity to expend energy, diminishes the degree of thoracic respiration. The factor that most frequently effects this is intestinal auto-intoxication, and this is exceedingly common, if not to some extent almost universal, in civilised communities.

Variation in the Respiratory Act in the Two Sexes.

Following up the question of respiration I studied the differences of the respiratory act in the male and female, and found that while the anatomist had regarded the pelvic bones as alone presenting distinctive characteristics, that the thorax of the female differs from that of the male in an even more obvious manner.[3] The variations presented by the female thorax are due to the fact that the abdomen, and indeed a portion of the thorax, have to accommodate the pregnant uterus for a certain period of time. This by its bulk interferes with the free descent of the diaphragm and impairs the entry of air into the lower segment of the thorax. To meet this temporary condition the respiratory capacity of the upper portion of the thorax must be increased. This is effected in a very simple manner. The sternum of the female is relatively shorter than that of the male. To it are attached seven and often six cartilages; in the male seven, and often eight, articulate with this bone. While this arrangement reduces the strength of the individual it renders the lower segments of the thorax more mobile and facilitates their separation by the pregnant uterus. While the whole sternum of the female is relatively shorter than it is in the male, the manubrium bears a very disproportionate relationship to the gladiolus, the latter being less than twice as long as the manubrium. In the male the manubrium is relatively small, while the gladiolus is always more than twice its length. Here, again, the woman sacrifices strength in order to enable her to perform her reproductive function. On the other hand, the upper costal arches are relatively much larger in the female, and owing to the greater length of the manubrium the first intercostal space is correspondingly deeper than in the male. By this arrangement she is enabled to aerate her blood sufficiently in the upper portion of her thorax when abdominal and lower thoracic respiration are hampered by her pregnancy.

Relation of Respiration to Vitality.

I cannot illustrate the importance of the bearing of the respiratory function on body growth and general vitality better than by giving the results of efficient respiratory exercises extending over a period of four months. The subject was a delicate child, whose respiration normally was entirely abdominal and whose pharynx showed marked adenoid growth. The following table represents measurements of the chest at the nipple level in its inspiratory and expiratory limits. These figures show that in four weeks the measurement on extreme inspiration showed an increase of 4 in., the expiratory limit remaining the same, while the weight had gone up 9½ lb. Three months later the inspiratory limit was 36 in., the expiratory had increased to 29½ in., and the weight was 9 st. 4 lb.;

[3] What are the chief factors which determine the differences which exist in the form of the male and female pelves? Trans. Obst. Soc., 1888.

TUMOUR OF THE RIGHT PETROUS BONE.

BY THOMAS ANWYL-DAVIES, M.B., B.S.LOND., M.R.C.S.

THE following case of tumour of the right petrous bone is of sufficient interest to merit a detailed description. The case was under the care of Dr. Hector Mackenzie, at St. Thomas's Hospital.

The patient, a baker of 47, was admitted to St. Thomas's Hospital with no family history of cancer, tubercle, or serious illnesses, a negative Wassermann reaction, and a denial of specific disease. Ten months previously all teeth were removed as the patient was run down; the doctor then discovered a lump in the right side of the neck near the angle of the jaw. This lump continued to grow, and the patient had pain below the right ear, which gradually extended upwards to the right side of the scalp and on to the right side of the forehead. About a month before examination he was troubled with diplopia; then the right eyelid began to droop, and three weeks later he was unable to open the eye. For a year he had been losing weight, and had had increasing deafness. When shaving he could not feel the razor on the right side, and when drinking the glass felt broken on that side. The patient had occasional headaches and slept badly owing to the tenderness of the scalp. There had been no vomiting, no noticeable weakness, no paræsthesia of the limbs, and nothing abnormal in his gait.

Examination.—The man appeared thin, not anæmic, and fairly cheerful. Right eye completely closed; obvious swelling in neck; skin smooth on right side of forehead; right angle of mouth drawn up owing to voluntary contraction of facial muscles round right eye. Temperature normal, pulse 72, and respiration 16. Heart and lungs: no signs of organic disease; urine normal. No apparent motor weakness in trunk and limbs, no sensory loss, no alteration of reflexes, no incoördination, astereognosis, dysdiadokokinesis, or ataxia.

Cranial Nerves.—First nerve: On testing with oil of turpentine, peppermint, and asafœtida there was definite loss of sense of smell on right side. Second nerve: Visual acuity with the L. eye V. = $\frac{6}{6}$, and with the R. eye V. = $\frac{6}{6}$. No sign of optic neuritis. Third, fourth, and sixth nerves: On attempting to follow the finger only a slight downward and outward movement remained, with a wheel-like rotation inwards, indicating a slight action of the superior oblique muscle. Right pupil slightly larger than left and inactive to light. Fifth nerve, first division: Slight blunting of sensation on forehead; second and third divisions, patch of complete anæsthesia over lower half of right side of face. The border ran horizontally below right eye, sloped outwards to angle of jaw, and ran along lower margin of jaw to mid-line and upwards over the lips. Chorda tympani division: Loss of taste on right side of tongue to salt, sugar, and quinine. Motor division: Paralysis of masseter and temporal muscles on right side. Seventh nerve: No apparent facial weakness. Eighth nerve: A watch could be heard at distance of 1 ft. from left ear, but not at all with right ear. Bone and air conduction were both affected on right side. Ninth, tenth, and eleventh nerves: Some weakness of tensor palati on right side. Deglutition normal; no aphonia; trapezius muscle weak. Twelfth nerve: Tongue showed slight atrophy and weakness on right side.

Summary of Cranial Nerves.—Complete paralysis of third, fifth, sixth; partial paralysis of first, fourth, eighth, ninth, tenth, and eleventh. There was a hard gland about the size of an egg between angle of jaw and anterior border of sterno-mastoid on right side, and a chain of hard, small glands along anterior border of right trapezius. An enlarged gland could be felt on the left side of the neck, on the anterior border of the sterno-mastoid, about the size of a small gooseberry. Two or three tender spots on right side of scalp, but nothing could be felt underneath them.

Diagnosis.—Here was a man who for the last year had had gradual enlargement of glands in the right side of the neck, and gradual paralysis of most of the cranial nerves on that side—especially the third, fifth, and sixth. The glandular growth was superficial, and from its position could not be affecting the fifth nerve, much less the nerves supplying the eye muscles. Therefore, to account for the paralysis of the cranial nerves, we had to assume either some internal connexion with the external growth or two separate lesions—i.e., a glandular swelling in the neck and an independent affection of the cranial nerves. The fact that the paralysis of the cranial nerves had, like the external growth, been slowly progressive and was synchronous with it, pointed to an intimate relation between the two. Moreover, the external growth and the paralysis were on the same side, the inference being that the paralysis of the cranial nerves was due to a deep-seated growth, which could not be seen or felt.

Situation of Growth.—If intracranial, the growth had to be either in the medulla or at the cerebello-pontine angle, or rising from bone or dura mater. If extracranial, the growth had to consist of at least four parts—the first affecting the third nerve in the orbit or spheno-maxillary fissure; the second affecting the third division of the fifth nerve below the foramen ovale; the third affecting the eighth nerve; and the fourth part affecting the ninth, tenth, and eleventh nerves. This scattered distribution made a single growth much more likely. If the growth were situated inside the skull a comparatively small lesion could affect several nerves arising close together. If medullary, the centre of the growth was evidently near the nucleus of the fifth nerve, because the fifth was the first nerve affected, but for anatomical reasons a medullary growth was extremely improbable, and unsupported by clinical evidence such as interference with the centres controlling the heart, respiration, temperature, or sugar metabolism. Arguments against a tumour at the cerebello-pontine angle were: absence of headache, vomiting, and optic neuritis, and no signs of pressure on the cerebellum, such as nystagmus, ataxia, weakness, or giddiness, or on the pyramidal tracts; the seventh nerve had escaped, and the third nerve, which is not in this region, was affected. The remaining position involved the petrous portion of the temporal bone. The third, fourth, and sixth nerves are in close proximity to the apex of the petrous bone, and the fifth nerve crosses the ridge of the petrous bone just external to the apex. The uncus, which is part of the olfactory path to the brain, is also in this neighbourhood. The posterior surface of this bone is related to the seventh and eighth, and also the ninth, tenth, and eleventh cranial nerves. The hypoglossal nerve is at least one-third below. Hence a growth, at most 1 in. in length, extending backwards from the apex of the petrous bone may affect all the cranial nerves, except the second and twelfth. In this patient, only the second, seventh, and twelfth nerves had entirely escaped; the immunity of the seventh was probably due to its superior powers of resistance, and because it lies on the eighth nerve and is separated by it from the bone. Moreover, the facial nerve on the right side was hyperexcitable, which is a preliminary stage to final paralysis. The indications were that the growth began just posteriorly to the apex of the petrous bone, and involved the fifth nerve; that it first spread backwards, injuring the eighth, and then began its forward expansion, destroying the sixth and third nerves.

Nature of the Disease.—The growth probably started in the bone or the dura mater covering the bone. The commonest new growths arising in these tissues are sarcomata and carcinomata; gummata, enchondromata, fibroid growths, and hydatid cysts are much less common; gliomata and tuberculomata very rare. Hæmorrhage was excluded by the slow progressive course of the disease, and abscess by the absence of pyrexia. In favour of malignant disease were the presence of enlarged glands in the neck and their characteristics, especially those along the anterior border of the trapezius; the steady progressive enlargement of both the glands and the intracranial tumour, coupled with a certain amount of general wasting during the past 12 months. The relatively slow rate of progress favoured carcinoma, while intracranial growths involving a large number of nerves often turn out to be sarcomatous. In the absence of signs in the lungs or viscera the seat of the primary growth was probably in the skull in the position described, the glands in the neck being secondary to it, the onset of the disease being about 18 months before admission. The impairment of the sense of smell may have been due to direct pressure of the growth on the uncus, but more probably to atrophic condition of the mucous membrane of the nose owing to paralysis of the fifth nerve, and the olfactory end-organs may have shared in the general atrophy.

Treatment.—Surgical treatment was impossible owing to the position of the primary growth and the extent of the secondary glandular enlargement. Medicinal treatment offered no more hope of success. The only treatment possible was symptomatic. Aspirin and bromides relieved the headache, while morphia was not needed.

Prognosis.—One can only expect further involvement of nerves, especially of the first division of the fifth and of the seventh. The close proximity of the cavernous sinus to the anterior part of the growth is a grave source of danger, and ulceration into it would lead to thrombosis and rapid extension of the growth, terminating in early death.

I am indebted to Dr. Hector Mackenzie and to Dr. G. T. Hebert, of the tuberculosis department of St. Thomas's Hospital, for permission to publish, and for assistance in this unusual case.

Park-place, St. James's, S.W.

produce what is called hæmolysis. If the serum immunised against the red blood corpuscles, and known as amboceptor, is not inactivated there is no need to employ the fresh serum of another animal, which receives the name of complement. Inactivation causes equal-sized protein particles to agglomerate partially, an action which always leads to a reduction of their Brownian movement, and may lead to a precipitation of some of the clumps formed. In the presence of antigen—that is to say, the substance with which the immunisation is carried out—the immune serum when used fresh and unheated will undergo similar changes, only more slowly, which is likewise the case when the serum is heated and complement is used. While these changes are taking place the surface-tension of the liquid medium is diminished, with the result that the red blood corpuscles give up their hæmoglobin. A specific amboceptor is not essential, because a simple negatively or positively charged colloid will take its place. Either colloidal silicic acid or colloidal aluminium hydroxide will replace the amboceptor. If the two are used together no hæmolysis results, because the iso-electric point is reached. There will also be no hæmolysis if one of the colloids is allowed to interact with the complement some time before the red blood corpuscles are added, because precipitation is the final stage of adsorption, agglomeration, &c., and when precipitation is complete, the normal surface-tension of the liquid medium becomes restored; consequently the added red blood corpuscles simply fall by their own weight to the bottom of the tube. The fresh serum of a guinea-pig is employed for the complement. In such a serum the protein particles are uniform in size and show vigorous Brownian movement. With colloidal silicic acid the particles decrease in number and rapidly form clumps, which finally become precipitated. During the stage of spontaneous condensation brought about by an increased positive charge, which in turn is produced on the surface of the particles by the non-metallic condenser, there occurs a diminution of the surface-tension, which causes hæmolysis of red blood corpuscles, if the latter are added before the surface-tension has rectified itself. Condensation leads to precipitation, which rights the surface-tension. The metallic conductor (aluminium hydroxide) causes the particles to increase in number and size and then to form small agglomerations. Condensation and final precipitation is the result, though the changes are slower in occurring. The metal causes condensation because the protein particles undergo a change to compensate for the dissipation of electrons and for the loss of certain electrolytes, while the non-metal causes condensation because from the start it leads to a conservation of the negative electricity. It is clear that hæmolysis is a surface-tension phenomenon, and that complement represents the normal electrification of the surface of the protein particles. Complex colloidal metals and non-metals will not act as amboceptor, because their action on the surface of the protein particles penetrates to the mass, and when this occurs precipitation is too rapid to register an alteration in surface-tension.

First Part of the Wassermann Reaction.

This is akin to the non-specific hæmolytic system, in which the protein particles constituting the complement, are precipitated before the red blood corpuscles are added. The patient's serum altered by inactivation and by the disease, adsorbs the antigen and tries to regain its normal state of emulsion at the expense of the complement. Failure to do so results in precipitation with consequent destruction of the complement, hence the amboceptor and red blood corpuscles, when they are added, also become precipitated—a positive W.R. A multitude of substances will act as antigen, and all capable of so acting have a common property in that they lower the surface-tension of the liquid medium in which the patient's protein particles are in true emulsion, and cause agglomeration and precipitation of the particles themselves.

Production of a Positive Complement-Fixation Test in Vivo.

If a single sub-lethal dose of an unprotected metal ($Al > Zn > Bi > Hg > Fe > Cu > Ag$) in the colloidal state is injected intravenously into a rabbit it makes the serum give a positive complement-fixation test (C.F.T.). Under the ultra-microscope the particles in such a serum are increased in number and a few are increased in size. The picture given resembles that of an early syphilitic serum, that of a serum to which a trace of alkali has been added, and that obtained at the negative pole when a current is passed through a serum film. If a lethal dose is injected the C.F.T. may be positive, negative, or anti-complementary, the result being largely influenced by the particular metal. There is a diminution in the number of the particles, a marked increase in size and clumping with actual precipitation. A similar picture is given by certain late syphilitic serums. If several injections of small doses are prescribed the serum gives a negative reaction, which usually becomes anti-complementary when too many are made; this is exactly what may happen in an early case of syphilis over-treated with arseno-benzene. Furthermore, the ultra-microscopic pictures obtained in both are identical—namely, marked diminution in the number of the particles, a few giant particles and clumps which evince a ready inclination to become precipitated.

If a single sub-lethal dose of a corresponding non-metal (belonging to the sulphur group of elements S, Se, & Te) is injected, the serum remains negative. If a lethal dose is injected the serum gives a positive C.F.T. and an ultra-microscopic picture similar to that obtained when a serum is treated with an acid, and to the picture witnessed at the positive pole when a current is first passed through a serum film. The particles are diminished in number and many agglomerations are formed, which in some instances are precipitated in masses. If several small doses are injected the serum becomes strongly positive with some preparations and anti-complementary with others, and the ultra-microscopic picture obtained is indistinguishable from that given by certain late syphilitic serums. Furthermore, the ultra-microscopic picture cannot be differentiated from that obtained with a serum changed by a metal, by a serum treated with an alkali, and by a serum at the negative pole during the passage of an electric current. The sequelæ of injecting a metal run, I believe, as follows. When the dose is sub-lethal the conductor effect of the metal causes the protein particles to discharge some of their electrons in the form of both electricity and heat. This would tend to increase the positive charge on their surface, a state of affairs which is incompatible with life. The amphoteric nature of the protein comes to the rescue and the " baseness " of the particles in increased.

This is the phenomenon of spontaneous condensation. Such a change makes the particles adsorb antigen and they readily go for complement with the hope of extracting therefrom the negative electricity they themselves have dissipated. This results in agglomeration and precipitation of all three and consequently a positive C.F.T. When a lethal dose is employed the discharge of negative electricity and increase of " baseness " may so affect the surface and mass as to render the particles incapable of adsorbing other particles, or as to augment their desire to recover their normal state to such a degree, that they are able completely to precipitate the complement particles without the assistance of the antigen, and give what is called an anti-complementary reaction. An anti-complementary reaction is the half-way house between a strong positive reaction and a negative reaction, because the C.F.T., like all colloidal reactions, is of a cyclical nature. When several small doses are injected the particles become dispersed and go into true solution, in which state they no longer act as colloids. Conversion into the molecular-dispersoid state is possible with a liquid-in-liquid colloidal system, After alluding briefly to the primary lesions and showing slides giving the less usual and common situations, Dr. Whitfield devoted himself to the cutaneous manifestations of the secondary and relapsing stages. Of these he showed practically a complete series of pictures, as well as a few microscopical sections, including psoriasiform syphilide and syphilitic lymphangitis of the face. He also discussed the differential diagnosis of the various lesions and some fallacies in former descriptions—e.g., the tuberculous nature of part of the corymbose rash. The last case described was that of a woman with a condition variously diagnosed as syphilis and lupus. It was completely cured by anti-specific remedies, but recurred later, following parturition, and was then cured by the Finsen light.

LONDON ASSOCIATION OF THE MEDICAL WOMEN'S FEDERATION.

A MEETING of this Association was held on Dec. 13th at the Elizabeth Garrett Anderson Hospital, Dr. LOUISA MARTINDALE, the President, in the chair, when papers on the subject of

Sterility

were read by Dr. CHRISTINE MURRELL and Dr. ELIZABETH BOLTON.

Dr. MURRELL ran briefly and systematically through the possible causes of the condition, emphasising at the outset the importance of considering the condition of the husband as well as of the wife. She said that where active spermatozoa are present in the seminal fluid, sterility may be due to incomplete or too rapid coitus, to mechanical obstruction to the upward passage of spermatozoa—as, for example, in cases of uterine displacement, cervical obstructions, or profuse discharge from or stenosis of the internal os. The uterine lining may be unsuitable for imbedding, or there may be disease of the tubes or of the ovaries. Apart from mechanical causes which could often be treated surgically there was still much work to be done in the study of the endocrine glands as they affect pregnancy. Dr. Murrell discussed at some length the hormone theory of sterility and the effects of administration of preparations of thyroid, posterior pituitary, thymus, and ovarian extracts on menstruation, ovulation and pregnancy, indicating the theoretical grounds on which the different endocrine preparations might be expected to be of value and the particular conditions in which she had found them useful.

Dr. BOLTON then read the following summary of 150 cases of sterility treated by her:—

I have put together the cases I have had in private of persons complaining of sterility after having been married more than two years. I have not attempted to get statistics from hospital patients, partly because of lack of time, partly because one does not get as fair a chance of talking with the patients and of advising examination of the husband as a preliminary measure. In all cases I try to find out what kind of life the patients lead, whether they tend to overwork physically or whether there is marked mental strain, also whether dyspareunia is present. This last condition is treated if present; in some cases dilatation with a stretching speculum is enough. In others I get the patient a graduated vaginal dilator and advise her to use it for half an hour daily for two months. In the extreme cases I examine the patient under an anæsthetic and dilate the vagina at one sitting. If possible, I prefer the more gradual methods. The frequency and time of connexion are then inquired into, especially in relation to the desires of the woman. To those who complain that there is no retention of semen I generally suggest the use of a bolster to raise the hips, and the alteration of position from the dorsal to the semiprone after intercourse.

I have notes of 150 cases examined, 28 of whom were seen once only and not treated. This leaves a total of 122 treated cases, of whom 63 became pregnant. On considering these cases I find they fall into four different groups according to the gynæcological findings, and I have found a gynæcological abnormality in all the 150 cases. 86 had marked anteflexion, the majority of these an elongated cervix pointing forward, 20 had retroversion, 28 fibroids, 16 were tube cases. Of the 86 anteflexion cases 16 were untreated; of the remaining 70, 40 became pregnant; 52 had a dilatation and curetting, 3 after trial of the passage of a sound—of these 27 became pregnant; 10 had a sound passed only and 10 became pregnant; 2 had vaginal septa and became pregnant later; 1 had injection of semen twice, after 2 dilatations, but with no result. One had an exploratory operation, when the ovaries were found to be adherent and freed, and a dilatation was also done, and this patient became pregnant. In all these cases the passage of the sound and dilatation were done, if possible, at such a time as to allow intercourse before the next period. The time of pregnancy in relation to the operation varies greatly—in the majority of cases it occurred within a few months, in a few cases at once, and in a few others after two to three years, but I have not heard of any after a longer period than three years.

Several of the dilatation cases were operated on on account of dysmenorrhœa as well as sterility, and many of these were much better from the point of view of the dysmenorrhœa, though they did not become pregnant. Of the 20 retroversions 2 were untreated, 13 of the 18 became pregnant; 11 were replaced and a Hodge pessary inserted; 4 of these had a dilatation, 2 had a sound passed. Of the 11 cases treated with a Hodge, 7 became pregnant. Two retroversions with adherent tubes had an exploratory laparotomy and both later became pregnant. Five Gilliam operations were done for sterility and 4 of these patients became pregnant. Of the 16 tube cases 3 were untreated, 13 had operative treatment, and 4 became pregnant. All these 4 had the right tube only involved, complicated by the appendix. Of the 28 fibroid cases, 7 were untreated; of the remaining 21, 7 became pregnant, 2 of these had a large polyp removed by the vaginal route, the other 5 had several fibroids removed by abdominal myomectomy. I usually advise myomectomy patients to avoid pregnancy for six months after the operation. I have had one patient from whom I removed two large fibroids by myomectomy who was found at the time to be about two months pregnant. She had had no previous pregnancy, had been married 14 years, and was 42. She went to term satisfactorily.

In considering this small number of cases Dr. Bolton thought it worth noting that all had a gynæcological condition that might account for the sterility; and that over 51 per cent. of the total treated cases became pregnant.

Anteversion Cases.

No. of Cases.	Age.	Time married in years.	No. of Cases.	Age.	Time married in years.

The above is a scheme of the cases of sterility showing age of patient and length of marriage. Cases italicised became pregnant.

and a strong positive serum either negative or anti-complementary. Practically speaking, any factor which causes the condensation of the protein particles may make a normal serum, and an early and late syphilitic serum behave as just described. It furthermore renders the protein particles more stable, a phenomenon which accounts for the facts, that a late syphilitic serum after the ingestion of alcohol is apt to give a negative C.F.T.; that the addition of sodium citrate fails to check coagulation; and that shock is prevented from following a second and what would ordinarily have been a lethal dose. The whole story is really that of a combat on the part of the protein particles—one of condensation versus dispersion.

Finally, I think we may conclude that a negative C.F.T. does not exclude syphilis, and that a positive C.F.T. means no more than that presumably the patient has had the disease.

THE SACHS-GEORGI REACTION IN SYPHILIS.

BY JAMES LAW BROWNLIE, M.D. GLASG., D.P.H., CAMB.,
ASSISTANT BACTERIOLOGIST, CORPORATION LABORATORY, GLASGOW.

THE very interesting contributions by Dr. A. Neave Kingsbury[1] and Dr. C. C. Okell[2] to the above subject have prompted me to present the following figures based on a comparative study of 500 serums submitted to the Wassermann (W.R.) and Sachs-Georgi (S.G.) reactions.

Method.—The W.R. was performed by Harrison's method, the S.G. in the simplest manner possible. Only one tube was used for each serum tested. The antigen was the same as employed in the W.R.—namely, three parts of a suitably diluted alcoholic extract of human heart muscle reinforced with two parts of a 1 per cent. alcoholic solution of cholesterin. The only difference was in the manner of adding the saline. For the W.R. the addition was made rapidly as recommended by Harrison, for the other the addition was made slowly. The opacity of the resultant emulsions varied accordingly. 0·3 c.cm. patient's serum was added to 1 c.cm. of antigen and the tube agitated to ensure complete mixing. The tubes were put in the ice-chest and readings were taken at 24 and 48-hour intervals. For practical purposes it was not found that the longer period produced any appreciable change in the appearance of the tubes, so that towards the end of the series the second reading was discontinued.

The serums used in the S.G. were quite unselected. During the investigation the number of specimens of blood submitted for the W.R. averaged 80. Considerations of time prevented the performance of both tests upon all each day but, as circumstances allowed, 20 to 40 were taken indiscriminately and tested as indicated above. It will be realised that by this means all circumstances governing the components of each test were exactly comparable. As the question of the use of inactivated as against uninactivated serum appeared to be at issue, 250 were tested with heated and 250 with unheated serum. Analysis of the results obtained in each instance did not provide sufficient data to warrant a definite pronouncement regarding the matter. It was, therefore, decided to combine all the results and present them as a record of a series.

TABLE I.

Total	..	S.G.+ W.R.+	S.G.− W.R.−	S.G.+ W.R.−	S.G.− W.R.+
500	..	206	199	52	43

Total agreement 81 per cent.

For simplicity of reference and for purposes of comparison I have taken the liberty (which I hereby acknowledge) of substituting my figures in the table so simply and effectively made out by Dr. Okell.

Apart from satisfying myself as to the comparative merits of the tests I was further interested to learn something of the respective values of each in varying clinical stages of syphilis. It must be understood that I was not responsible for the diagnoses. I accepted the statement of the practitioners submitting the specimens. In Table II. I have attempted to show how the 95 disagreements in the series were related to the specified stage of the disease. It will be seen that the S.G. gave a greater percentage of positive readings in primary, secondary, tertiary, and central nervous system syphilis; the W.R. in old treated cases and familial syphilis; whilst the results balanced in congenital syphilis and in gonorrhœal cases. Under the conditions of experiment outlined it appeared that, unlike Dr. Okell, with a negative W.R. the S.G. was not so seldom positive as to enable me to confirm his opinion that "where the Sachs-Georgi was used in place of the Wassermann only a small percentage of patients would be unnecessarily submitted to treatment."[2] I had not viewed the S.G. in this light as, judging from most of the clinical histories provided, I came to the conclusion that the S.G. was more delicate, especially in primary and early secondary syphilis. Such a point, however, I would not be inclined to strain as it is based upon a relatively small number of cases. I have no doubt that the more complicated modifications indicated by Dr. Okell were responsible for his excellent percentage agreements, but it appeared of interest to record that satisfactory figures were obtainable in the extremely simple manner indicated. After all, the ideal longed for by every worker in this branch of serology is simplicity, and substitution tests are only attractive the more nearly they approach to that ideal. From a purely practical point of view, one wonders what advantage alternative tests have over the Wassermann reaction. Greater specificity has not yet been proved for them and their introduction into routine work merely serves to cause confusion.

TABLE II.

GENERAL PRACTITIONERS AND MIDWIVES.—The Ministry of Health will shortly hold a conference with the County Councils' Association on points arising out of the scale of fees payable to medical practitioners under Section 14 of the Midwives Act, 1918. The London County Council has been invited to send representatives and has decided that the members of its Midwives Acts Committee shall attend.

Reviews and Notices of Books.

STUDIES IN THE PALÆOPATHOLOGY OF EGYPT.

By Sir MARC ARMAND RUFFER, C.M.G., M.D.Oxon., late President of the Quarantine Council of Egypt. Edited by ROY L. MOODIE, Ph.D., Associate Professor of Anatomy in the University of Illinois. Chicago: University of Chicago Press. 1921. Pp. 372. $7.50.

THIS beautiful volume is designed as a memorial tribute to the big-hearted and cosmopolitan pathologist who lost his life during the war. Born in Lyons of a French father and a German mother, educated at Oxford and University College, London, Ruffer was a pupil of Pasteur and Metchnikoff at the Pasteur Institute, and was first Director of the British Institute of Preventive Medicine in Cairo. Ruffer spent most of his life in Egypt, where his wonderful gift of tongues, his gentleness and urbanity, and his wide sympathies enabled him successfully to carry on the difficult task entrusted to the polyglot body known as the Sanitary, Maritime, and Quarantine Council of Egypt. In this work his gifts of diplomacy and tact and his cosmopolitan culture found scope for their expression.

Visiting the Government Medical School in Cairo in 1908 at a time when the work of investigating the pathology of the ancient human remains from Egypt and Nubia was in progress, Ruffer became smitten with the desire to participate in this task. Before then it had been the practice to submit ancient Egyptian pathological material that called for histological or bacteriological examination to Prof. S. G. Shattock, at the Royal College of Surgeons of England, or to Profs. A. R. Ferguson and A. Looss or Dr. Charles Todd in Cairo, but in 1909 Sir Marc Ruffer seriously tackled the problem of devising a technique for the histological examination of tissues in some cases as much as 60 centuries old. After laborious experimentation he at last achieved success, and it is a striking tribute to his skill and patience that he was able to obtain such remarkable histological preparations of the tissues and organs of mummies and predynastic bodies and demonstrate the presence of bilharziosis in ancient times. But he was so fascinated by this technical achievement that he did not pay sufficient attention to the wider problems opened up by his methods. He does not seem to have formulated any scheme of organised investigation or to have got any sense of historical perspective. As a consequence, his work adds little to our knowledge of the history of pathological conditions. Indeed, the view he gives us of the incidence of disease in ancient Egypt is partial and misleading, and questions of chronology are not given adequate consideration.

Sir Marc Ruffer was one of those gentle diplomatists who was ready to take other people at their own valuation. In this volume many erroneous statements are made on the strength of misleading information supplied to him by others. One instance of this is of sufficient practical importance at the present time to call for special reference. This is the "Study of Abnormalities and Pathology of Ancient Egyptian Teeth," published posthumously in the *American Journal of Physical Anthropology* and reproduced as a chapter in this book. The claim made on p. 207 as to the common occurrence of dental caries in predynastic Egyptians is utterly misleading. This affection was extremely rare in Egypt until the latter part of the Second Dynasty, and it was not really common (and then only in the upper classes) until the time of the Pyramid Age (Fourth Dynasty).

The book has been produced by Lady Ruffer and the work of editing these reports was entrusted to the sympathetic care of Prof. Roy Moodie, of Illinois, who has performed his task as well as one unfamiliar with Egyptian conditions could do it. In a volume of such dimensions there are singularly few misprints. A mistake that was made in the Proceedings of the Royal Society of Medicine (1920) has been repeated in this volume; the portraits of Thutmose I. (*Plate* LXV.) and Thutmose IV. (Plate LXIV.) have been exchanged.

The University of Chicago Press is to be congratulated on the excellence of the printing and illustration of this volume and for undertaking the publication of this memorial of, and tribute to, a fine man.

LABORATORY EXAMINATIONS.

Comment Interpréter en Clinique les Réponses du Laboratoire? Par HUGEL, DELATER, and ZOELLER. Paris: A. Maloine. 1922. Pp. 139. Fr.5.

THIS handy little book sets out to tell the practising medical man how to set about getting laboratory investigations made and how to interpret the answers which he gets. The instructions given are clear, definite, and sufficiently dogmatic; some specimens he can obtain himself, in other cases (e.g., blood counts) he is wisely told to fetch a technical expert to the patient's bedside. Similarly, the deductions he may draw from the results are put shortly and pointedly, and the book concludes with a catalogue of what laboratory examinations may usefully be made in each disease. The ideal which the book serves is not perhaps a very high one—it savours too much of the penny-in-the-slot machine—but making allowances for slight differences between French and English fashions and practice it should be useful in a field which we may hope improvements in medical education will soon make obsolete. There is a good index—not too common a feature in French books. The title page is dated a year in advance—this may be a misprint.

HYGIENE OF WOMEN AND CHILDREN.

By JANET E. LANE-CLAYPON, M.D., D.Sc. Lond., Dean and Lecturer on Hygiene in the Household and Social Department, King's College for Women. London: Henry Frowde and Hodder and Stoughton: 1921. Pp. 351. 15s.

IN the early days of hygienic activity the energy of the workers was directed mainly toward devising and promoting measures for improving the environmental conditions of the people, and it would be difficult to exaggerate the immense advantage to our national health that has resulted from their labours. The provision of pure and wholesome water-supplies, better means of excrement disposal, reform of scavenging arrangements, and improvement in housing conditions were among the first problems to receive attention. The isolation in hospital of the infectious sick, the prevention by means of well-devised schemes of sanitary administration at the ports of the introduction into the country of infectious diseases from abroad, and the supervision of the milk- and food-supplies have all contributed to great improvement in the public health. In later years another phase of hygiene developed, which concerned itself with the care of the individual rather than of his environment, and resulted in the institution of schemes for the medical inspection of school children, the treatment of patients suffering from tuberculosis and venereal diseases, and for maternity and child welfare.

It is with the last-mentioned sphere of public health activity that Dr. Lane-Claypon deals in the book under review. She maintains that of all the time-saving devices known the best and most effective is knowledge coupled with experience. If the proper way of doing a thing is known much less time is taken over it, and, as experience is gained, the nervous system works more quickly and a further reduction in time is brought about. The chapter on fresh air and ventilation is instructive and embodies the results of recent scientific work on this subject. The question of the influence on health of the prevalence of dust and dirt in towns is fully considered. In a table showing the relative amount of soot and dirt deposited per square mile in different towns and areas, that at Malvern is lowest, being only 78 tons per square mile per annum. The

Medical Societies.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.

An ordinary meeting of this Society was held on Dec. 16th at 1, Upper Montague-street, London, W.C., Dr. Herbert Jones (M.O.H., Herefordshire Combined Districts) being in the chair in the absence of the President, Dr. W. J. Howarth, who was absent through indisposition. Nineteen new members and seven associates were elected.

Surg. Rear-Admiral Sir Percy W. Bassett-Smith delivered an address, as President of the Naval, Military, and Air Force Hygiene Group, on the

Development of Hygiene, Pathology, and Bacteriology in the Naval Medical Service,

in which he first gave a retrospect of the service. In 1602 barber-surgeons were appointed to the Navy, at first as "pressed men," and in 1704 surgeons in ships ranked with pilots and carpenters, being allowed as a favour to mess with warrant officers. In 1808 the senior medical officer alone messed in the wardroom. In those days hygiene was not of much account. Sir James Lind, senior physician of Haslar Hospital, was the pioneer of hygiene in the Navy, and his name would always be famous for his work in the prevention of scurvy, which he stated caused more deaths in the fleets than the French and Spanish arms. He recommended lemon-juice and sauerkraut, and introduced the distillation of sea-water, better ventilation and drying of ships, improved clothing and cleanliness, and fumigation with sulphur and arsenic. Next to Lind as a hygienist reformer came Sir Gilbert Blane, physician to the fleet (d. 1834), who strongly supported vaccination against small-pox. In 1801 80 naval surgeons presented Jenner with a gold medal, but vaccination was not made compulsory in the Navy until 1858. In 1827 Sir Wm. Burdett was medical director-general and instruction for medical officers was instituted. Dr. Scott founded the pathological museum at Haslar, and gave clinical lectures and instruction in the post-mortem room. This ceased in 1840, and the instruction of naval surgeons was not seriously taken in hand until 1871, when they were sent to the Army School at Netley. In 1881 the Naval Medical School was started at Haslar Hospital. In 1900 tropical medicine was added to the course of study, and special encouragement was given by the presentation of medals and the granting of accelerated promotion. Voluntary courses were added for senior men who studied but were not subjected to examinations, and this was a great success. Research work was encouraged by the Admiralty, and Lord Selborne, First Lord, took much interest in the work for the prevention of Mediterranean fever. In 1912 the Medical School was moved to the R.N. College, Greenwich, so as to be in touch with other centres in London. About 1900 medical officers in the fleet were supplied with a bacteriological box, and later with microscopes, water analysis boxes, and facilities for the tuberculin test, the preparation and use of vaccines, the detection of the spirochætes of syphilis, and the use of the Wassermann test.

The speaker referred to the work done with Haldane's apparatus in connexion with the ventilation of ships and submarines, and to the examination of shaving brushes for anthrax, of which a series of cases occurred during the war. Many of these were suspected to be cerebro-spinal fever, but anthrax bacilli were found abundantly in the fluid obtained by lumbar puncture. Not infrequently gastro-intestinal disease attributed to food poisoning had to be investigated epidemiologically and bacteriologically, and the speaker alluded to an outbreak at the Royal Naval School, Greenwich, involving 127 boys, and shown to be due to the *B. suipestifer* (mutton type). Since the war much experimental work had been done at Greenwich to find a substitute for lime-juice which had been found so inefficient an antiscorbutic, and good results had been obtained with lemon-juice concentrated in vacuo without heat, and with tinned tomatoes. The importance of laboratory work was now fully recognised in the Navy, especially in connexion with tropical diseases, and laboratories had been provided not only at the three great naval hospitals and at Greenwich, but also in all foreign hospitals and to a less extent in the smaller sick quarters and infirmaries. A body of sick-berth men had been trained for laboratory work. They had a six months' course and an examination, and were given extra pay; they were enthusiastic in their work. Another development was the greater facility now given to naval officers to take post-graduate diplomas, such as the D.P.H., D.T.M., and the degrees of doctor, &c. The possession of the D.P.H. was now registered in the Navy List as an honourable mention, and was a sine qua non for the appointment of naval health officer at the great ports and certain other posts.

The chief problems in the Navy at the present time were physical training, and the prevention of venereal disease and tuberculosis. Improvement had taken place in recent years in connexion with tuberculosis owing to the better ventilation of ships and better control of the food-supplies, but there were still far too many cases. All infective cases were invalided and the M.O.H. of their home address informed. The speaker advocated an increase in rank and pay for the professors at the Medical College at Greenwich, who should be appointed, respectively, as directors of hygiene and of pathology, responsible to the medical director-general for all naval laboratories throughout the country.

Major-General Sir W. Macpherson, in proposing a vote of thanks, welcomed Sir Percy Bassett-Smith as President of the Group. He spoke of his association with him in the South African War in the equipment of hospital ships, when his enthusiasm and energy were boundless. He had been the chief instrument in the development of preventive medicine in the Navy in recent years.

Col. Commandant W. W. O. Beveridge (Director of Hygiene, War Office), in seconding, said that great progress in naval hygiene had been made since the war. The appointment of naval health officers had been a most important step. He had found that they worked in close coöperation with the War Office.

Surg.-Commander R. St. G. S. Bond (R.N. College, Greenwich) spoke of his association with Sir Percy Bassett-Smith, and alluded to the improvements in the facilities for study which he had brought about.

Dr. P. Caldwell Smith (M.O.H., Wandsworth) referred to an old book by Surg.-General Pringle (1740) on "Diseases of the Army," and said that the conditions in the Army at that time were evidently as bad as in the Navy.

Dr. C. Sanders (M.O.H., West Ham) regretted that there was not a huge audience of students and of the exalted authorities from all countries to hear of the success of the course of practical work and instruction without examination.

The Chairman said that Sir Percy Bassett-Smith's communication had emphasised the success of the new group, and would foster the spirit of coöperation not only between the medical officers of the three forces, but also with civilian medical officers.

SOUTH-WEST LONDON MEDICAL SOCIETY.

Syphilis.

A meeting was held at Bolingbroke Hospital on Dec. 7th, when Dr. A. Whitfield gave a lantern lecture on Syphilis.

sang par les glandes à sécrétion interne ou glandes endocrines." This section contains only three references, to the names of Pende, Lévi, and Bordeu! No less than 83 pages are occupied by the subject of Hydrogeology. It is evident from the list of references at the end of each section, where the names of the authors are almost invariably to be found, that this book contains merely matter in which they are especially interested, and is not a dictionary in any true sense of the term. Had the work been written under a title such as "Gleanings of Biologists in the Domain of Physics," and strung together by some sort of thread, it would possibly have been more interesting, and would certainly have been more welcome.

Some Micro-Chemical Tests for Alkaloids. By CHARLES H. STEPHENSON, Scientific Assistant, Bureau of Chemistry, U.S. Department of Agriculture, Washington, D.C. Including Chemical Tests of the Alkaloids Used, by C. E. PARKER, Assistant Chemist, Bureau of Chemistry. London: Charles Griffin and Co., Ltd. 1921. With 27 plates (162 photomicrographs) and a folding Table of Reactions. Pp. 106. 21*s.*

THE authors have examined various reactions of 51 alkaloids in order to obtain microchemical tests. Some of the reactions are very sensitive and characteristic; in other cases the results are satisfactory though not all that might be desired; only three alkaloids gave no reaction. Photomicrographs of all the more important crystalline precipitates are shown in a series of excellent plates. Most of the work was done between 1907 and 1910, and the results have been published in preliminary communications which are now welded together for the first time. Full acknowledgment is given to other workers who have published data on microchemical tests. The authors' tests were made in concentrations of 1 in 1000 to 1 in 50, except in the case of quinine, which did not yield satisfactory crystals in solutions less concentrated than 1 in 35. A list of reagents is given, followed by an account of methods and a general scheme for identification. The tests of 51 alkaloids with 35 reagents are summarised in a table at the end of the book, which must be regarded as a valuable contribution to the subject, and is sure to be welcomed by those engaged in the work of identifying alkaloids.

TECHNIQUE OF THE TEAT AND CAPILLARY GLASS TUBE.

Second edition. By Sir ALMROTH E. WRIGHT, M.D., F.R.S., Principal of the Institute for Pathology and Research, St. Mary's Hospital, London, with the Collaboration of LEONARD COLEBROOK, M.B., B.S. Lond., Assistant, Bacteriological Department, National Institute for Medical Research. London: Constable and Co. 1921. Pp. 384. 42*s.*

DURING the nine years since the first edition of this work appeared the technique of the teat and capillary glass tube has been pressed into service in the unravelling of many new problems. The second edition is in every way a bigger book, longer by 173 pages, larger in size, wider in its sphere of application, and broader in its conception. It is now described as a handbook for the medical research laboratory and the research ward.

The value of the methods described lies in the fact that they can all be carried out with minimal quantities of reagents, a matter of considerable importance on occasion, as when it is desired to study the blood at frequent intervals. There are many additions and improvements. The fourth chapter, dealing with general principles of the technique, has been elaborated and new methods of considerable interest are described. To Chapter VII. have been added three valuable clinical appendices. The first deals with the clinical significance of increased and diminished blood coagulability and on the method of correcting these conditions. The second deals with the pathology of acidosis, and in particular with the part that this plays in shock, gas gangrene infection, and scurvy. The third treats of the physiological significance of the antitryptic function of the blood, and will appeal, by reason of its suggestions of methods of treatment, to the practising surgeon as well as to the research worker. The original methods described in Chapter X. for the study of the emigration and other biological functions of leucocytes will be of interest and service to biologists, physiologists, and pathologists. The illustrations of this chapter are masterpieces of lucidity and detail.

In Chapter XI. are described techniques for the study of the place of origin and source of the protective substances elaborated in the organism. The introductory remarks that "everything that relates to this department of research is in a quite inchoate condition" prepare us for a rather involved chapter, and we wonder if the coining of such terms as "aipsĕro-epiphylactic response" will prove helpful or otherwise to most readers. Chapter XII. admirably describes the techniques elaborated by the authors during the late war for the study of infected wounds. To this chapter are appended some suggestive remarks on the phenomena of diffusion and osmosis.

The book is lavishly illustrated with admirably executed drawings and coloured plates by Mr. A. Kirkpatrick Maxwell. Altogether the work is a notable production which we confidently commend to all engaged in medical research.

AIDS TO MEDICINE.

Third edition. By BERNARD HUDSON, M.D. Camb., M.R.C.P. Lond., Swiss Federal Diploma, Physician in charge of the English Sanatorium at Montana, Switzerland. London: Baillière, Tindall and Cox. 1921. Pp. 370. 4*s.* 6*d.*

THE third edition of this small book has been enlarged to include a chapter on diseases of the skin. The primary object of the author, the production of a revision book of a convenient size for the student to carry about, has been successfully accomplished, but the real *raison d'être* for a new edition—the rejuvenescence of contents—has not been met. Without increasing the size of the volume the subject matter could have been brought up to date in many respects, when it would have proved of more value to students desiring to effect a rapid revision of their work.

HEREDITY.

Erblichkeitslehre und Rassenhygiene. Band I. *Menschliche Erblichkeitslehre.* By Prof. ERWIN BAUR, Prof. EUGEN FISCHER, and Dr. FRITZ LENZ. Munich: J. F. Lehmanns. 1921. Pp. 305. 11*s.*

This is the first or introductory volume of what is intended to be a fairly complete compilation on the subject of heredity, especially in relation to national health and eugenics. This part deals with the scientific and fundamental aspect of heredity, leaving the national aspect for the second volume. The book is divided into four sections, distributed among the three authors, the first of whom, Prof. E. Baur, describes the principles and laws of variation and heredity. Under the heading of Myxovariation the theory of Mendel is explained, with numerous of the standard examples from crossing experiments on plants and animals. By paravariation is meant difference within the normal range, but with no tendency to transmission to offspring, and by ideovariation the spontaneous evolution of differences capable of transmission—mutation—of which the classical example is the evolution of a new species of evening primrose. The three types of variation are described, without the addition of any new material. In the second section, Prof. E. Fischer describes, somewhat superficially, the differences met with between the existing races of man. The evolution of man from his anthropoid ancestors is also dealt with, and some attempt is made to show the relationships between the existing branches of the human race. This section is unduly condensed into less than 70 pages. In the third and

LIVERPOOL MEDICAL INSTITUTION.

A meeting of the Pathological Section of this Institution was held on Dec. 8th, Dr. J. E. **Gemmell**, the President, being in the chair, when Prof. J. M. **Beattie** read a paper on

Encephalitis Lethargica.

Prof. Beattie dealt mainly with the pathological conditions found in encephalitis lethargica, basing his remarks on the post-mortem examination of three cases. The main pathological changes found were the congestion, both in the membranes and in the cerebral tissues, and the perivascular infiltration with occasional hæmorrhages in the Virchow-Robin space. The nerve cells showed degenerative changes—pigmentation, eccentricity or loss of nucleus, vacuolation, &c. Neurophagia was present, but only in a minor degree. Irregular rounded or oval bodies, sometimes with an apparent central spot, were seen in the nerve cells, but these were thought to be degeneration products and remains of Nissl granules. Very large numbers of " hyaline bodies," described by Boyd and by various Italian observers, were demonstrated, especially in one case (a woman. aged 48 years), but they were present also in the other cases (aged 54 and 19 respectively). The relation of these to corpora amylacea was discussed, and Prof. Beattie concluded that the bodies were produced by degeneration of myelin, that they had no proved ætiological significance in the disease, as stated by some of the Italian workers, but that their presence could not be regarded as accidental or as having no special pathological relation to the virus of encephalitis. It was shown in one case, where the first symptom was ophthalmoplegia, that these bodies were present in considerable numbers in the optic nerve, and especially associated with a perivascular infiltration of the sheath of the nerve. The bacteriological findings, and the experimental production of the disease were discussed. Reference was made to the recent communication of Delaunay suggesting that encephalitis lethargica was a form of rabies, and the similarity between the pathological findings in the two diseases was dealt with. The relationship of the disease to poliomyelitis and to influenza was also discussed.

Prof. Beattie concluded that the disease was a distinct entity, that the naso-pharynx and salivary secretion harbour the virus, and that therefore it was important that throat and nose disinfection should be urged. He made an appeal for a coöperation between the pathologist, the bacteriologist, and the physician in the investigation of this disease, both during life and in the post-mortem room, and especially urged that the post mortems should be undertaken only by thoroughly trained and experienced pathologists.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

A meeting of this Society was held at the General Infirmary, Leeds, on Nov. 25th, in conjunction with the Leeds Branch of the British Dental Association, Sir **Berkeley Moynihan**, the President, in the chair.

Dr. **Bertram Watson** opened a discussion on

Oral Sepsis and Systemic Disease.

After referring to Dr. William Hunter's pioneer work, the speaker said he purposed dealing mainly with chronic apical infection, probably the most important of the focal infections. He briefly alluded to Rosenow's work on selective localisation of bacteria, and described the changes found at the apices of infected teeth, emphasising that these conditions are frequently symptomless, and only discoverable by dental radiography. Dr. Watson enumerated various systemic disorders which may be attributed to oral sepsis, laying stress on malignant endocarditis, nephritis, and the rheumatic group of diseases. He concluded with a plea for closer coöperation between physician, dental surgeon, and radiographer, and for a fuller recognition of the potentialities of dental work.

Mr. H. B. **Scargill** explained the methods used in the X ray examination of the teeth, illustrating his remarks by numerous lantern slides.

Dr. **Sinclair Miller** dealt with the Pathology and Bacteriology of Oral Sepsis. He described the various types of gingivitis and pyorrhœa alveolaris, and expressed the opinion that other factors as well as bacteria were essential for the production of these conditions. In speaking of apical and peri-apical infections of the chronic type, Dr. Miller quoted his bacteriological findings in a large series of teeth condemned by X ray and removed from patients suffering from systemic disease with a view to vaccine therapy. Streptococci, falling chiefly into the viridans group, were obtained from all specimens of the series; other organisms in addition were cultured in a small percentage of the cases. Dr. Miller demonstrated slides of bacteria lying in granulomatous tissue removed from the apices of infected teeth.

Mr. G. A. **Phillips** said that though Dr. Hunter's work had led to a proper appreciation of the damage caused by septic conditions in the mouth, there appeared to be grounds for complaint in some quarters against the increasing sacrifice of teeth in the treatment of certain systemic disorders. After discussing the mode of origin of peri-apical infection and chronic suppurative periodontitis, Mr. Phillips stated that many dentists had doubts as to the results of devitalisation of pulps and of attempts at disinfection or preservation of asepsis in root canals by the use of caustic and antiseptic drugs. He pointed out that the difficulty might be met by the use in an aseptic root of a neutral filling material and, in cases where antiseptics are required, by drainage and redressing at short intervals, removing all traces of drugs before introducing the permanent filling. He expressed doubts as to whether complete confidence should be placed in radiograms; the dentist should require reasonable proof of the need for sacrificing any large number of teeth. Mr. Phillips entered a plea for a wider exercise of caution and thoroughness in diagnosis.

Mr. G. L. **Wilkinson** said that while there was perhaps no positive proof that focal abscesses or granulomata at the apices of the teeth were often the cause of infected hearts and joints, a large quantity of circumstantial evidence had been presented during the last few years. He asked that these cases should be considered without prejudice and with a close coöperation between physician and dentist. He entered a strong plea for a careful conservative treatment, pointing out that areas of rarefaction, as shown by radiology, disappear after infection is removed. He advocated as suitable for front teeth the method of amputation of the necrotic apex through the outer wall of the alveolar process after filling of the canal with some hard and suitable material.

Health Exposition in New York.—A public exposition of the way in which various official departments and charities work together to promote public health was held in New York from Nov. 14th–19th. About 50 social service and charity organisations were represented, and means of combating preventable disease occupied a prominent place.

Association of Infant Welfare and Maternity Centres.—Lady Barrett recently addressed the Workers' Section of this Association on Birth Control, and Miss Margaret French has suggested that the Workers' Section should adopt a definite policy on this matter. This suggestion will be discussed at a special meeting to be held early in January. The next conference of the Workers' Section will take place at the Midwives' Institute on Jan. 27th, at 8 P.M., when Dr. Eardley Holland will lecture on Causes of Neo-natal Death.

THE LANCET.

LONDON: SATURDAY, DECEMBER 24, 1921.

The International Standardisation of Sera.

THE Conference held by the Health Committee of the League of Nations on the standardisation, for international purposes, of sera and serological tests was an extremely satisfactory one. Good work was done, and the foundations were laid for its continuance and extension. A difficult set of agenda was dealt with seriatim, and unanimous conclusions were arrived at by sub-committees of men specially chosen by the countries which they represented because of their personal experience. The recommendations of these sub-committees will be found on p. 1339 of this issue of THE LANCET. In several directions they represent an agreement to undertake definite comparative studies, and the result of these is to be finally submitted to the State Institute for Serotherapy of Copenhagen, of which the director is Prof. MADSEN, the chairman of the Health Committee of the League of Nations. The sittings of the Conference will be resumed in about six months' time, probably at the Institut Pasteur in Paris, when progress will be reported and further understandings can be reached.

The international character of medicine has been widely recognised in connexion with the incidence of certain epidemic diseases; that the progress and spread, for example, of plague, cholera, and yellow fever, throughout the world ought to be made the subject of international control has long been recognised. It is generally assumed that, with regard to these diseases, international notification, at least, is well established and systematically carried out. Certainly agreements have been executed between various countries for their mutual protection against the spread of such epidemics, and such agreements rest on the basis of fraternal notification. We hope, however, that it will fall under the health responsibilities of the League of Nations to keep official sanitary authorities everywhere alive to the necessity of this notification as an essential preliminary to the surrounding and stamping out of these diseases; for unfortunately there is little doubt that in some cases international notifications have not hitherto been conscientiously made, in the matter notoriously of plague and cholera. But there are other diseases whose spread from nation to nation is not so obviously preventable by notification but against which common weapons are none the less required and should be made available by the health organisation of the League of Nations. Such are the six great diseases which are, to a varying extent, amenable to serum treatment, or for which serological tests are essential—namely, diphtheria and tetanus, various types of pneumococcic and meningococcic infection, dysentery, and syphilis. But not only do different nations adopt a different protective technique in the employment of sera or in their serological tests, but sometimes the same nation has difficulty in making up its mind which of two or three methods to adopt. It was a most practical move on the part of the Health Committee of the League of Nations to begin its new duties by making an attempt to arrive at international standards in these matters, and it will be seen by our report of the Conference what excellent progress has been made.

The Dull and Backward Child.

PROMINENT features in the annual report of the Chief Medical Officer of the Board of Education have been dealt with in our columns, but we may well go back to this interesting document to consider that part of the report in which Sir GEORGE NEWMAN deals with the dull and backward child. For the dull and backward child often presents difficult and delicate problems to the practitioner, and the lessons to be learnt from the problems presented by our State-educated children are applicable in principle to children of every social status. The curricula of the senior departments of public elementary schools are so arranged that a child entering at the age of 7 years should progress yearly to such an extent that he deserves promotion to the standard above; thus his last year of elementary school would be spent in the highest standard. It has long been known that this ideal has not been reached, but until recently, as far as we are aware, the extent of deviation from this aim has not been measured. A recent investigation, however, into the educational ability of the entire body of children in a representative London borough has shown that barely one-half (46·4 per cent.) are assigned to a standard assumed as normal for their age. When the ability of a child is only equal to that of a "normal" child two years younger than himself the backwardness becomes of real importance. Unfortunately, at least 10 per cent. of the senior school population, the report informs us, present this degree of backwardness, a figure which accords with that arrived at by the medical members of the Education Reform Council, as shown by their report published in 1917. Expressed in round figures, it means that half a million children attending public elementary schools in England and Wales are definitely backward, and constitute potential waste products of the education system. We do not suggest that the same evidences of failure would be forthcoming from those large private schools, which are always known as "the public schools," but even these schools have their dull boys who have managed to scrape through the entrance examination. Those who fail to pass are dealt with by the smaller private schools or receive more individual teaching from tutors. The State elementary school population represents some six-sevenths of the total school population, and it is more than probable that a considerable number of children educated elsewhere belong to the dull and backward group.

The position has for some years received the attention of school medical officers. The late Dr. A. H. HOGARTH, when school medical officer for Buckinghamshire, and subsequently Dr. C. W. HUTT, when working at Brighton, made some inquiries by which this part of the Chief Medical Officer's report is supported, and the results of three valuable inquiries made last year are also incorporated in the report. A detailed extract is quoted from the annual report of Dr. H. P. NEWSHOLME, county medical officer for the North Riding, which deals with the number of defects present in the large number of backward children examined. A classification was not made of the causes of backwardness, apart from physical and mental, nor does the extract quoted inform us as to the number of children presenting combined physical defects, an omission which leaves vague the practical conclusions to be drawn. Information along these lines may yet, we hope, be made available for general use. The manner in which backward children have been dealt with in Croydon and highest figure is that for Glasgow, where it is estimated as 1330 tons, while in London, at Buckingham Gate, it reached 500 tons. The information given on food and diets is up to date and allots to modern work on vitamins an adequate space. Dr. Lane-Claypon's remarks on the use of alcohol are, as a whole, founded on common sense and experimental results, but she makes certain general statements on the subject, the accuracy of which is at least open to question. On p. 185, for example, the following paassge occurs: "Anyone who will take the trouble to make observations will readily discover that the most alert people, who preserve the elasticity of their mind and body with advancing years, are those who do not take alcohol. Those who early lose their muscular agility, and whose minds get set, will usually be found to take alcohol habitually, although not necessarily in large amounts." She makes some interesting remarks on the "psychological aspect of dress," and attaches more importance to clothes as an expression of personality than is usually accorded to them.

On the whole, Dr. Lane-Claypon has produced an excellent book which can be recommended to health visitors, and indeed to all who are interested in the health of mothers and young children.

PRINCIPLES AND PRACTICE OF SURGERY.

By Dr. A. HERMAN HAUBOLD, Clinical Professor in Surgery, New York University. London and New York: D. Appleton and Company. 1921. In two volumes. With 633 illustrations. Pp. 2482. 81s.

THIS work is a result of the thoughtful consideration and laborious toil of an experienced surgeon. The book contains much detailed information in a small compass. Few recent advances have been left unnoticed, and the judgment of the author in selection is admirable. The whole of surgery, general and special, is included in two volumes, which contain profuse and well-chosen illustrations. The insertion of special chapters on Biology, Anatomy, Physiology, Pathology, and Bacteriology takes up space which might, perhaps, have been better used, but a reminder of these subjects may well be needed by the young surgeon. We applaud the details of surgical practice enunciated by Dr. Haubold; discussion of the principles of surgery, as we understand them, seems less satisfactory. For example, wound repair is considered apart from inflammation, certain resemblances being recognised, but modern views hardly allow of such separation. Again, every form of "itis" is here described as if it were more or less of a special entity, and different forms of inflammation are called catarrhal, suppurative, putrid, phlegmonous, gangrenous, &c. No student should be taught in this manner if confusion of mind and hopelessness of outlook are to be avoided. A student must be impressed with the essential similarity between inflammatory processes throughout the body; that by the careful study of a boil he can unravel the pathological happenings in an inflamed tonsil, appendix, or prostate, and that in an inflamed conjunctiva he can watch the changes which occur in inflamed serous and synovial cavities.

As further examples of the form of teaching adopted in this book, we would draw attention to the absence of general principles in dealing with the hollow muscular viscera and the tubes of the body. From the description of the symptoms and signs of chronic obstruction due to gall-stones the student might easily gather that the gall-bladder and duct follow a special law of their own instead of conforming to the general behaviour of hollow muscular coated viscera and tubes; all of them hypertrophy, thicken their walls, and contract their cavities when opposed to a surmountable obstacle; all of them dilate and become thin-walled when the obstacle they are up against is insurmountable.

It is only fair to say, in comparing this book with standard English works, that many of these equally neglect fundamental principles, but it is so important for teachers to impart and for students to equip themselves with these principles that to point out their significance is an obvious duty. It is for this reason that we would recommend Dr. Haubold's work to surgeons rather than to students, for the former will have grasped the principles underlying their craft and will find in these volumes much suggestive material for their guidance in the solution of difficult problems.

BIOCHEMISTRY.

Practical Physiological Chemistry. Third edition. By J. A. MILROY, M.A., M.D., Lecturer on Biochemistry, Queen's University, Belfast; and T. H. MILROY, M.D., B.Sc., F.R.S.E., Professor of Physiology, Queen's University, Belfast. London and Edinburgh: W. Green and Son, Ltd. 1921. Pp. ix.+449. 21*s*.

THE rapid growth of biochemistry necessitates frequent revision of the text-books dealing with this subject. In the present edition of this work matter suitable for the use of senior students has been added. The more advanced portions and all the practical exercises are set in different type from the rest of the book, part of which is of necessity theoretical. A few references are also given. The instructions for the practical work appear to be clear and adequate, though the general impression given by the work is that it represents the result of successive graftings on to an original and apparently rather ancient stock of class-notes. Rather too little has been cut away at each graft of new material, with the result that there is too great a variety of methods. Thus, two methods for preparing glycogen from liver are given; at least eight methods for the estimation of glucose, and three for the volumetric estimation of chloride in urine may also be mentioned as examples. Among the valuable newer methods are the colorimetric method for determination of hydrogen-ion concentration, the determination of the phosphate ratio of the urine (the method of calculation of which might have been given more clearly), the determination of amino-nitrogen, and various colorimetric methods of quantitative analysis. It is to be regretted that the authors found that space would not allow of a proper treatment of the physiological applications of gas analysis, because no senior student's course is complete without some acquaintance with these methods, on which so much of modern physiological views are based. The addition of tables and schemes for analysis complete a very useful book. The authors would be well advised, in the preparation of a future edition, to provide a critical friend with a copy of the book and a blue pencil, and to give him carte blanche; such a test of friendship would furnish us with one of the best books on the subject of physiological chemistry which any teacher could desire.

Dictionnaire de Biologie Physiciste. By ALBERT and ALEXANDRE MARY. Paris: A. Maloine and Fils. 1921. Pp. xvi.+408. Fr.40.

THE general conception of this work is doubtless excellent; physical and physico-chemical aspects of biological problems figure largely in the programme of modern investigation, and an encyclopædic dictionary dealing with the more important of these questions and giving such references as would enable further inquiry to be pursued, would be valuable to many. On reference to the work before us, expectations, however hopeful, are speedily disappointed, for it is little else than a rag-bag of out-of-the-way information of all sorts, and, since most of the matter is not even up to date, it can fulfil no useful purpose. For example, there is no section on electricity, radium, or fluorescence; the section dealing with osmosis is antiquated both from the biological and physico-chemical standpoints; nothing is said of recent work on luminescence. The general degree of accuracy which prevails can be judged from the following extract: "*Hormones*—Starling a donné le nom d'hormones aux produits colloïdaux versés dans le

RUSSIAN FAMINE RELIEF.

Sir Arthur Stanley, as chairman of the British Red Cross, and Lord Emmott, as chairman of the Russian Famine Relief Fund, have written to the press in support of the National Appeal for the starving millions in Russia. "We wish to make it quite clear," they say, "that while, with the support of the British public, we can do something to save life and to mitigate suffering, it will not be possible for us to deal fully with famine on such a colossal scale as that which unfortunately now exists in Russia. If food is to be brought to the starving population as a whole; if worse famine next year is to be avoided by adequate sowing; above all, if the accompanying epidemics are to be combated at their source and not allowed to spread to surrounding countries, a sum of many millions is needed." They go on to express the hope that a special area or objective may be allotted, small at first, but increasing with the available resources, on which British relief efforts may be concentrated to real purpose. With this object in view they have secured the services of Sir Benjamin Robertson, the eminent Indian famine expert, who is proceeding to Russia forthwith as British Commissioner. The Red Cross Societies and other organisations in India and the Dominions have agreed that any assistance they can give shall be sent through the British Red Cross and Famine Relief Fund, acting on the advice of Sir Benjamin Robertson, and in this way it will be ensured that the relief that goes from the British Empire as a whole will be concentrated as far as possible on one specific objective.

BENJAMIN MARTEN, PIONEER.

A YEAR ago, as Dr. Charles Singer reminded us in his recent Chadwick lecture, there passed unnoted and uncelebrated the bicentenary of a remarkable work, the "New Theory of Consumptions: more especially of a Phthisis or Consumption of the Lungs, wherein . . . Enquiry is made concerning the Prime, Essential and hitherto accounted Inexplicable Cause of that Disease, so very Endemick to this Nation, . . ." by Benjamin Marten, M.D. Instead of marking a revolution in epidemiology, the book scarce raised a ripple on the stream of contemporary thought, and its author pursued his unknown course in his "House in Theobald's Row, near Red Lyon Square in Holbourn," whence his work is dated Sept. 1st, 1719. Of his life we know little. He was not a Member of the Royal College of Physicians, and his doctorate of medicine does not appear to have come to him from an English university. He was obviously well acquainted with the literature of his subject, and quotes freely from the writings of the new microscopists. Already in the fifteenth century Hieronymo Frascator had suggested minute seeds as the cause of infection and the instrument of contagion, and in the blaze of light thrown by the use of the microscope there were not wanting speculations as to the possible connexion between animalcules and disease. But Marten towers above all others for boldness of inspiration and clarity of exposition. Having reviewed historically the theories of infection, he dismisses them as inadequate, and proceeds to set forth, with remarkable insight, the germ theory as we hold it to-day. It is of particular interest to note that he applied his conception to syphilis, rheumatism, leprosy, small-pox, measles, plague, and the common cold, but refrains from committing himself on the subject of cancer.

Some quotations from his book will speak more eloquently for him than any historian can do.

"The *Original* and *Essential Cause* then, which some content themselves to call a vicious Disposition of the Juices, *others a salt Acrimony, others a strange Ferment*, others a malignant Humour (all which seem to me dark and unintelligible) may possibly be some certain Species of *Animalcula or wonderfully minute living Creatures, that*, by their peculiar Shape, or disagreable Parts, are inimical to our Nature: but, however, capable of subsisting in our Juices and Vessels, and which being drove to the Lungs by the Circulation of the Blood, or else generated therefrom their proper *Ova* or Eggs, with which the Juices may abound, or which possibly being carried about by the Air may be immediately conveyed to the Lungs by that we draw in, and being there deposited as in a proper *Nidus*, or Nest, and being produced *into Life*, coming to *Perfection*, or increasing in Bigness, may by their spontaneous Motion, and *injurious Parts, stimulating and perhaps wounding or* gnawing the tender Vessels of the Lungs, cause all the disorders that have been mentioned, viz., a more than ordinary Afflux of Humours, upon the Part, Obstruction, Inflammation, Exulceration, and all other the *Phenomena* and deplorable Symptoms of this Disease.

"And it is reasonable to suppose that there are various Species of *Animalcula*, so of course they are of various Magnitudes, of different Shapes, and have peculiar Parts . . . so various Diseases, *more or less sudden and pernicious, may* be caused (by them).

"For how can we better account for the regular types the Small-pox, Malignant, and all other Continual and Intermittent Fevers, as well as many other Distempers, keep and the peculiar Attributes and *Crises, etc.*, they have than by concluding they are severally caused by innumerable *Animalcula*, or exceeding minute Animals that variously offend us according as their Species are different, and as their peculiar *Shape and Parts* are more or less *injurious to our* Fluids and Solids. . . .

"*By what has been said*, I think . . . there is possibly no Ulcer or Ulcerated Matter, but what is stock'd with *Animalcula*.

"But I would not be understood to advance that all Distempers are caused by them; I would urge only the possibility and likelihood of their being the Essential Cause of the Plague, Pestilential and other malign Fevers, Small-pox and some other *Diseases as well Chronick as Acute and* particularly of that dreadful one a *Phthisis* which is the *peculiar Subject of these Papers*.

"If the Air we breathe, the Food we eat, or Liquor we drink in common with the rest of Mankind, were full of such minute living Creatures or their seed, then we might *reasonably suppose* that all Persons Breathing, Eating, and Drinking of the same, would in like Manner be more or less liable to the same Distemper, which would in that Case become Epidemical and almost *Universal, this therefore* we may imagine to happen in the Case of Plagues and Pestilential *Distempers, that seize* upon whole Cities, Towns, and Countries, at a Time, but not very likely in the Case of the Disease we now treat of (i.e., Phthisis).

"It seems much more probable that the minute Animals or their Seed, which we have supposed to be the Essential Cause of a *Phthisis* or Consumption of the Lungs, are for the most part either convey'd from Parents to their Offspring *Hereditarily*, or *communicated immediately from distemper'd* Persons to sound Ones who are very conversant *with them*; the *first* way has been already mentioned when we were speaking of the Small-pox . . . the last way, which is properly called Infection, we may conceive to be the more reasonable, if we consider how quickly and easily some other Distempers are communicated from one Person to another, as the Itch, Venereal Disease, etc., which are yet very far from becoming universal.

"It may be therefore *very likely, that by an habitual* lying in the same bed with a Consumptive Patient, *constantly* Eating *and* Drinking with him, or by very frequently *conversing so near*, as to draw in part of the Breath he emits from his Lungs, a Consumption may be caught by a sound Person; for it may be reasonable to suppose that if the Blood and Juices of such distemper'd People, be charged with vast quantities of *Animalculæ* as I have conjectur'd, then their profuse Sweats, and their Breath, may be likewise charged'd with *them, or their Ova or Eggs*, which by that means may possibly be convey'd into the Bodies of those who lie, or are most conversant with them.

"It may here probably be objected, that if the Disease is communicated after this Manner few that come near a Consumptive Person would escape having that Distemper; but *in Answer* to this I imagine that slightly conversing with Consumptive Patients, is seldom or never sufficient to catch the Disease; there being but few if any of those minute *living Creatures or their* Eggs communicated in slender conversations, and which if they are, may not perhaps, be produced into Life, or be nourished or increas'd, in the new Station they happen to be cast; besides, we may imagine that some Persons are of such an happy Constitution, that if any of the *Ova* of the inimicable minute Animals that fourth sections Dr. F. Lenz reviews the collected knowledge on diseases which are in any way transmissible, and though the list is not complete much interesting material has been set forth, illustrated by numerous genealogical tables. The fourth section deals mainly with heredity in mental and psychopathological conditions, with some remarks on the heredity of genius, and the mental attributes of certain races.

The bibliography is considerable, though certain omissions are apparent. The authors have adopted the useful plan of giving with each reference a brief note of the contents of the work consulted. The sections by Dr. Lenz are likely to appeal to those medical men who are only interested in heredity in so far as it is manifested in disease.

PHYSICAL SIGNS IN THE CHEST AND ABDOMEN. By A. J. JEX-BLAKE, M.A., M.D. Oxon., F.R.C.P. Lond., formerly Physician to St. George's Hospital and Assistant Physician to the Hospital for Consumption, Brompton. London: J. & A. Churchill. 1921. 9*s.* 6*d.*

IN this publication Dr. Jex-Blake has kept clearly in view the wants of beginners in that fundamental branch of medicine with which his book deals, yet the medical practitioner and senior student will find many interesting points elucidated in the paragraphs of small type freely scattered through the volume. Several physical signs which are especially puzzling to the student receive explanation; thus it is pointed out that the diminished vocal fremitus which is sometimes met with over a consolidated lower lobe in a case of lobar pneumonia really depends on an accumulation of secretion in the bronchi, and that, after a bout of coughing sufficient to empty the air tubes, the more typical "increased vocal fremitus" will reappear. In like manner many pitfalls are guarded against, and sound advice in carrying out the physical examination of the patient is given. It is a matter for regret that uniformity in the nomenclature of abnormal physical signs is still far to seek, and we are glad to note that Dr. Jex-Blake makes increase in the *clearness* of the transmitted sound the essential criterion of pectoriloquy. He closes with a chapter devoted to a consideration of the more important abdominal swellings.

The book is concerned with ordinary physical examination and intentionally contains no account of the use of the sphygmomanometer, polygraph, electrocardiograph, or Rontgen rays in diagnosis. The illustrations consist of outline diagrams and useful graphic representations of heart-sounds and murmurs, and the whole forms a concise and lucid introduction to an essential branch of medical practice.

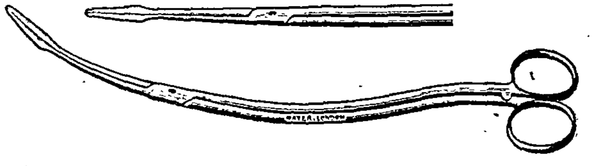
JOURNALS.

ARCHIVIO DI PATOLOGIA E CLINICA MEDICA. Vol. I., No. 1. October, 1921. Pp. 102. Bologna: Casa Editrice, L. Cappelli.—This new periodical has just been issued under the joint editorship of Prof. Luigi Zoja of Pavia, Prof. G. Viola, and Dr. F. Schiassi of Bologna, to whom we wish every success in their enterprise. There are four papers in the opening number, each followed by a résumé in French for the benefit of readers who are not familiar with the Italian language. Prof. Viola contributes an essay on the principles of diagnosis in which he incorporates the views of many other distinguished observers. For him a purely anatomico-pathological doctrine is untenable; the seat of disease cannot be isolated from other changes in the organism, and medical science must hold a just balance between the anatomical and functional elements in diseases. For him, also, a diagnosis must necessarily be differential, whether it is direct or intuitive, automatic or analytical, or rational. He admits three forms of ontrol—i.e., the history, the maxim of Bacon ablata causa tollitur effectus," and quantitative judgment. He asks the question, Is medicine a science or an art? and solves it by answering that it is both—a science in its diagnostic and an art in its therapeutic aspect. His main conclusion is that a mechanical clinical doctrine has had its day and must be replaced by a Hippocratic psychophysical doctrine.—Dr. A. Crosti contributes some original observations on the pathological and clinical aspects of artificial pneumothorax with woodcuts of its macroscopic and microscopic results on the lung tissue. He describes these results in a case of multiple pulmonary abscess and two cases of phthisis, which showed the development of bundles of connective tissue of pleuritic, vascular, bronchial, and interstitial origin.—Dr. R. Grignani discusses the hæmoglobin metabolism in nephritis; his researches point to a frequent oligochromocythæmia, not due to hydræmia alone nor to increased destruction of red cells, but to their inadequate formation. Hence an insufficient diet contributes to the production of anæmia.—Dr. Schiassi describes in a practical article the clinical use of the refractometer. He prefers one of the Pulfrich type and discusses alterations of the refraction index in various diseases and the part it plays in the investigation of the hæmoclasia crisis lately described by Widal and others occurring in disturbed hepatic function. The journal is well printed and is of quarto size and presumably will be issued monthly, but this is not distinctly stated, and we have searched in vain for any indication as to its price.

New Inventions.

TENDON TUNNELLING FORCEPS.

THE forceps shown in the accompanying illustration have been designed for the purpose of making subcutaneous tunnels and pulling tendons through them in the operation of tendon transplantation, the idea being to have an instrument so flattened and tapered as to pass easily through the subcutaneous tissues and, at the same time, act as a forceps. In performing tendon transplantation for musculo-spiral paralysis I use them in conjunction thus: having detached the tendon of the flexor carpi radialis from its insertion and exposed part of its belly and the commencement of its tendon in the upper third of the forearm through a short incision, and the tendons of the extensores ossis metacarpi and brevis pollicis near the wrist through a similar incision, the point of the curved pair of forceps is passed in subcutaneously at the lower angle of the former and pushed obliquely towards the latter where it is brought into view. The forceps is opened and the subcutaneous space widened sufficiently to accommodate the portion of the muscle belly detached from the surrounding intermuscular septa. The straight forceps is then passed from the incision at the wrist alongside the curved pair which is withdrawn. The tendon of the flexor carpi radialis is then pulled from its natural tunnel and its end being grasped in the straight forceps is pulled along the new tunnel. The same procedure is adopted in dealing with the flexor carpi ulnaris. I have found the curved forceps particularly useful in dealing with a case where the elbow is ankylosed at a right-angle.



The instruments have been made by Messrs. Mayer and Phelps, New Cavendish-street, London, W.

RUSSIAN FAMINE RELIEF.

Sir Arthur Stanley, as chairman of the British Red Cross, and Lord Emmott, as chairman of the Russian Famine Relief Fund, have written to the press in support of the National Appeal for the starving millions in Russia. "We wish to make it quite clear," they say, "that while, with the support of the British public, we can do something to save life and to mitigate suffering, it will not be possible for us to deal fully with famine on such a colossal scale as that which unfortunately now exists in Russia. If food is to be brought to the starving population as a whole; if worse famine next year is to be avoided by adequate sowing; above all, if the accompanying epidemics are to be combated at their source and not allowed to spread to surrounding countries, a sum of many millions is needed." They go on to express the hope that a special area or objective may be allotted, small at first, but increasing with the available resources, on which British relief efforts may be concentrated to real purpose. With this object in view they have secured the services of Sir Benjamin Robertson, the eminent Indian famine expert, who is proceeding to Russia forthwith as British Commissioner. The Red Cross Societies and other organisations in India and the Dominions have agreed that any assistance they can give shall be sent through the British Red Cross and Famine Relief Fund, acting on the advice of Sir Benjamin Robertson, and in this way it will be ensured that the relief that goes from the British Empire as a whole will be concentrated as far as possible on one specific objective.

BENJAMIN MARTEN, PIONEER.

A YEAR ago, as Dr. Charles Singer reminded us in his recent Chadwick lecture, there passed unnoted and uncelebrated the bicentenary of a remarkable work, the "New Theory of Consumptions: more especially of a Phthisis or Consumption of the Lungs, wherein . . . Enquiry is made concerning the Prime, Essential and hitherto accounted Inexplicable Cause of that Disease, so very Endemick to this Nation, . . ." by Benjamin Marten, M.D. Instead of marking a revolution in epidemiology, the book scarce raised a ripple on the stream of contemporary thought, and its author pursued his unknown course in his "House in Theobald's Row, near Red Lyon Square in Holbourn," whence his work is dated Sept. 1st, 1719. Of his life we know little. He was not a Member of the Royal College of Physicians, and his doctorate of medicine does not appear to have come to him from an English university. He was obviously well acquainted with the literature of his subject, and quotes freely from the writings of the new microscopists. Already in the fifteenth century Hieronymo Frascator had suggested minute seeds as the cause of infection and the instrument of contagion, and in the blaze of light thrown by the use of the microscope there were not wanting speculations as to the possible connexion between animalcules and disease. But Marten towers above all others for boldness of inspiration and clarity of exposition. Having reviewed historically the theories of infection, he dismisses them as inadequate, and proceeds to set forth, with remarkable insight, the germ theory as we hold it to-day. It is of particular interest to note that he applied his conception to syphilis, rheumatism, leprosy, small-pox, measles, plague, and the common cold, but refrains from committing himself on the subject of cancer.

Some quotations from his book will speak more eloquently for him than any historian can do.

"The *Original* and *Essential Cause* then, which some content themselves to call a vicious Disposition of the Juices, others a salt *Acrimony*, others a *strange Ferment*, others a malignant Humour (all which seem to me dark and unintelligible) may possibly be some certain Species of *Animalcula* or wonderfully minute living Creatures, that, by their peculiar Shape, or disagreeable Parts, are inimical to our Nature; but, however, capable of subsisting in our Juices and Vessels, and which being drove to the Lungs by the Circulation of the Blood, or else generated therefrom their proper *Ova* or Eggs, with which the Juices may abound, or which possibly being carried about by the Air may be immediately conveyed to the Lungs by that we draw in, and being there deposited as in a proper *Nidus*, or Nest, and being produced into Life, coming to Perfection, or increasing in Bigness, may by their spontaneous Motion, and injurious Parts, stimulating and perhaps wounding or gnawing the tender Vessels of the Lungs, cause all the disorders that have been mentioned, viz., a more than ordinary Afflux of Humours, upon the Part, Obstruction, Inflammation, Exulceration, and all other the *Phenomena* and deplorable Symptoms of this Disease.

"And it is reasonable to suppose that there are various Species of *Animalcula*, so of course they are of various Magnitudes, of different Shapes, and have peculiar Parts . . . so various Diseases, more or less sudden and pernicious, may be caused (by them).

"For how can we better account for the regular types the Small-pox, Malignant, and all other Continual and Intermittent Fevers, as well as many other Distempers, *keep and* the peculiar Attributes and *Crises, etc.*, they have than by concluding they are severally caused by innumerable *Animalcula*, or exceeding minute Animals that variously offend us according as their Species are different, and as their peculiar Shape and Parts are more or less injurious to our Fluids and Solids. . . .

"By what has been said, I think . . . there is possibly *no Ulcer or Ulcerated Matter, but what is stock'd with Animalcula.*

"But I would not be understood to advance that all Distempers are caused by them; I would urge only the possibility and likelihood of their being the Essential Cause of the Plague, Pestilential and other malign Fevers, Small-pox and some other Diseases as well Chronick as Acute and particularly of that dreadful one a *Phthisis* which is the peculiar Subject of these Papers.

"If the Air we breathe, the Food we eat, or Liquor we drink in common with the rest of Mankind, were full of such minute living Creatures or their seed, then we might reasonably suppose that *all Persons Breathing, Eating*, and Drinking of the same, would in like Manner be more or less *liable to the same Distemper*, which would *in that Case* become Epidemical and almost Universal, this therefore we may imagine to happen in the Case of Plagues and Pestilential Distempers, that seize upon whole Cities, Towns, and Countries, at a Time, but not very likely in the Case of the Disease we now treat of (i.e., Phthisis).

"It seems much more probable that the minute Animals or their Seed, which we have supposed to be the Essential Cause of a *Phthisis* or Consumption of the Lungs, are for the most part either convey'd from Parents to their Offspring Hereditarily, or communicated immediately from distemper'd Persons to sound Ones who are very conversant with them; the first way has been already mentioned when we were speaking of the Small-pox . . . the last way, which is properly called Infection, we may conceive to be the more reasonable, if we consider how quickly and easily some other Distempers are communicated from one Person to another, as the Itch, Venereal Disease, etc., which are yet very far from becoming universal.

"It may be therefore very likely, that by an habitual lying in the same bed with a Consumptive Patient, constantly *Eating and Drinking* with him, or by very frequently conversing so near, as to draw in part of the Breath he emits from his Lungs, a Consumption may be caught by a sound Person; for it may be reasonable to suppose that if the Blood and Juices of such distemper'd People, be charged with vast quantities of *Animalculæ* as I have conjectur'd, then their profuse Sweats, and their Breath, may be likewise charged'd with them, or their *Ova* or Eggs, which by that means may possibly be convey'd into the Bodies of those who lie, or are most conversant with them.

"It may here probably be objected, that if the Disease is communicated after this Manner few that come near a Consumptive Person would escape having that Distemper; but in Answer to this I imagine that slightly conversing with Consumptive Patients, is seldom or never sufficient to catch the Disease; there being but few if any of those minute living Creatures or their Eggs communicated in slender conversations, and which if they are, may not perhaps, be produced into Life, or be nourished or increas'd, in the new Station they happen to be cast; besides, we may imagine that some Persons are of such an happy Constitution, that if any of the *Ova* of the inimicable minute Animals that

Manchester merits attention. At Croydon certain backward children were selected and taught in small classes in the hope that they would be able more or less to resume their normal place on the ladder of educational attainments. In Manchester much the same plan has been adopted, but younger children, who were being taught in Standard I. in neighbouring schools, were selected. The making of arrangements of this sort by an education authority might well be considered a practical measure and constitute in a large sense a medical solution of some of the difficulties in the education of the backward child.

A point which should receive consideration is whether, in certain more or less special circumstances, those children of weak general ability who are all round mentally inefficient, but not sufficiently deficient as to be classed as mentally deficient—the very "thickheads"—should not be taught in a special class, associated, it may be, with an ordinary public elementary school rather than in a special class for mental defectives. Children such as these would seem to require tuition of a different character from the mentally deteriorated. It is at present difficult to differentiate between the teaching these children should receive and that given to mentally defective children, but the formation of such a class might help to provide the proper training for the backward child, and also create valuable medico-psychological knowledge. The material for such classes can be found in any thickly populated centres.

Public Health in Egypt.

LIKE many other matters in Egypt, the health organisation of the country is at present undergoing a radical change. Progress must necessarily be slow, but that a beginning has been made is evident from a perusal of Lord ALLENBY's report as High Commissioner for 1920, the medical portions of which have been summarised in two recent issues of THE LANCET.[1] In accordance with the recommendations of the Commission, which sat under the presidency of Dr. ANDREW BALFOUR during the summer of 1918, the director-general of the Department of Public Health has now become an Under Secretary of State for Health, and so enjoys a far more influential position than formerly; the deputy-director has now become director-general; and a new post of inspector-general has been created to which, we learn with satisfaction, an experienced Egyptian has been appointed. These changes in the higher personnel no doubt augur well, but they must be regarded merely as a beginning, for the recommendations of the Balfour Commission cover every aspect of health administration throughout the country, and extend even to the village and the doings of such humble officials as sanitary barbers. When the scheme is complete, there will be a technical adviser and director of medical intelligence to assist the Under Secretary and the director-general; also directors of (1) Sanitary Services, (2) Epidemic Services, (3) Medical Services, (4) Lunacy, (5) Medical Education, (6) Public Health Laboratories, and (7) Sanitary Engineering, and in addition a secretary-general who will control personnel, registration of vital statistics, and similar matters; all these officials to be responsible to the director-general. In this way it is hoped the directorate will be relieved of many trivial matters of detail.

A knowledge of Egypt and a study of Lord ALLENBY's report indicate that many preventable diseases still maintain their firm hold upon the country. It is a matter for congratulation that the reduction in the incidence of small-pox is as great as 60 per cent. when compared with the figures of the previous year, and from the fact that over ten million doses of vaccine lymph were prepared in the Vaccine Institute during 1920 against half that number in the previous 12 months, it is obvious that a systematised attempt is being made to reduce this scourge. There is apparently to be a general campaign against ankylostomiasis and schistosomiasis, and could these two diseases be appreciably reduced, the increased working capacity of the fellahin would amply repay the capital outlay. Pellagra as an equal drain on the energies of the labourer might well receive attention by those engaged in the attack on the two worm infections. These efforts on the part of the authorities, and many similar ones which are dealt with in the report, read excellently on paper, but as long as the success of their execution depends entirely on administrative reforms, very little improvement is likely to result in the health and happiness of the toiler in the fields, upon the value of whose work the prosperity of Egypt rests. What is essential in addition to administrative reforms is an educational campaign and an attempt to convince the people of the country at large that the disabilities from which they suffer are mainly preventable, but only with the coöperation of every member of the community. Are there signs that such a campaign is in progress or contemplated?

A consideration of the health situation in the Soudan is full of interest. As in Egypt, so in the Soudan, small-pox has been of considerable importance of late. Malaria, on the other hand, stands out in far greater prominence than in Egypt, and a comparison of the diseases prevalent in the two countries shows that there are many striking differences in the relative importance of the various infections demanding attention. The desert has proved an effectual barrier between these two populous areas in the past, but improved communications and the migration of labour, necessitated by the present scheme of Soudan development, have resulted in a changed situation; there is likelihood that much disease will be spread from one country to the other unless adequate precautions are taken to prevent this. To meet the needs of the case, labourers passing from Egypt are now detained in a quarantine camp at Halfa, and there are medically examined, shaved, bathed, disinfected, and treated with a vermifuge. This is a step which appears to have been taken only just in time, and it is to be hoped that no slackness will be permitted in the execution of such measures in the future. Should the worm diseases of Egypt be allowed to spread and tak as firm a hold on the population in the cotton-growin areas of the Soudan and exercise an influence a baneful as in Egypt, the authorities will be alone t blame. Another infection which it is essential t control is tuberculosis. The Soudanese show ver little resistance to this disease, and when infect usually succumb; the spreader of infection exis for so short a time that little harm results, a the tubercle rate in the Soudan appears to be lo. Egyptians, on the other hand, show a far higher resistance and, in consequence, chronic centres of the disease may be established in the Soudan should those infected be undetected and rejected at the frontier. Such an introduction of tubercle into the Soudan might prove as great a calamity as did the infection of the negro in the Southern States of America.

---

[1] THE LANCET, Dec. 3rd and 10th, pp. 1195 and 1254 respectively.

of these 13 cases showed that the average duration of the disease was only 2–3 years, whereas the average duration of the bilateral cases was as great as 4–6 years. Hence the conclusion that, given time, many, if not all, of these unilateral cases would become bilateral. A third subject to which Prof. Petrén gives prominence is the remarkable success which can be achieved by passive movements under skilled supervision. He does not ignore such well-known remedies as massage, salicylates by the mouth, and heat in various forms, but he regards them as secondary in importance to passive movements. These should be so powerful as often to cause considerable pain, but this matters little provided it passes off quickly. As judged by the X rays, the results he obtained were not very impressive. Very different was the functional improvement often obtained, and it is obvious that patients are more interested in improvement they can themselves gauge, than in the cheerless and rigidly objective evidence of skiagrams. Though it is evident that Prof. Petrén has made extensive use of the X rays, he accepts their showings with a healthy modicum of reserve, and as the records of some of his cases show, he does not abandon all hope of restoring mobility to a joint even when the X rays point to "complete synostosis." In one such case passive movements enabled the limb to be flexed about the hip to 20°–30° without the slightest movement of the pelvis; and the patient, a man aged 77, was able to walk with two sticks on his discharge from hospital. It is probable that the immobilisation effected by arthritis deformans of the hip is not due solely to changes in the bones and articular cartilages, but also to a considerable degree to muscular spasm. And this is the component of the forces limiting the movements of the joints which responds so satisfactorily to skilled, systematic treatment.

VETERINARY HEALTH SERVICE IN FRANCE.

THE diminution of over 50 per cent. in cases of rabies notified in Paris and the Department of the Seine for the year 1920 is encouraging, especially as the figures for the four quarters of the year were 144, 108, 47, 34, showing a constant decrease; the 333 cases recorded included 326 dogs, 6 cats, and 1 bear. The total number of cases in France has also been reduced by 1807, giving a diminution of 39 per cent. on the 1919 figures; 2136 persons were bitten by dogs and other animals in 1919, of whom 6 died; only 1403 were bitten in 1920, with 1 death.

The annual report by Prof. H. Martel on the French Veterinary Service of Paris and the Seine Department shows how vigilantly the public health is protected also from other diseases of animal origin in this district. The incidence of tuberculosis in animals does not decrease, and more efforts should be concentrated on methods of prevention. Prof. Martel states that the intra-dermic method of testing for tuberculosis is the one most favoured by cowkeepers. Tuberculosis has been fairly common in pigs, especially those which have been kept in boarding schools, orphanages, and institutions, and the authorities stress the necessity of cooking scraps of human food in order to check the prevalence of tuberculosis in young pigs. The frequency of tuberculosis in fowls is a matter of some import; of 657 fowls suspected and examined 342, or 52 per cent., were found to be tuberculous. The incidence of glanders has increased slightly, but it is gratifying to know that out of 1165 horses and 119 mules imported not one reacted to the mallein test. Great care is taken to cleanse and disinfect trucks used in animal transport by the use of steam and sodium hypochlorite. Damaged and putrefied carcasses have been the chief causes of seizure and destruction of fowls, geese, ducks, turkeys, lambs, goats, pigeons, and rabbits. One of the most noteworthy points in Prof. Martel's report is the good work done in the inspection of the egg supply. It is probable that in this country real benefit would accrue from a thorough examination of the supply of eggs to be offered for sale. In France over 2½ million eggs were thrown out by the inspectors as unfit for human consumption. The shadow test seems to be the one chiefly relied on to discern the quality of the egg. The October supply of eggs was the most faulty, because at this time the preserved eggs are put on to the market. In April exotic eggs are rare, and the country supply shows good quality. Apparently but little bad food escapes the vigilance of the French Veterinary Service, and this important branch of the Public Health Service seems to be very efficiently managed.

BLOOD TRANSFUSION FOR BURN SHOCK.

SEVERE burns occurring in infants and young children are always apt to terminate fatally from shock. In the *Canadian Medical Association Journal* for October Dr. Bruce Robertson has reported encouraging results obtained at the Hospital for Sick Children, Toronto, from transfusion in the treatment of severe burns in children. The greater number of severe burns admitted occurred in children of 4 years and under. The mortality has been high (35 per cent.), not so much from the primary shock as from secondary toxic shock. Weiskotten found in fatal cases of superficial burns characteristic lesions in the suprarenals, lymphatic tissues, and heart muscle "indicating the presence of a more or less specific poison in the circulating blood" (*Jour. Amer. Med. Assoc.*, Jan. 25th, 1919, p. 259). It seems that a toxin is produced in the burned tissue and is thrown into the blood stream. Its action diminishes after about three days. It is significant that all the patients in the hospital who succumbed to shock did so in about 60 hours. Dr. Robertson thinks that in this period treatment should be directed towards neutralisation or elimination of the toxin. The injection of saline and glucose solutions, with the idea of diluting the toxin and of hastening elimination of the toxin, has been tried, but in the more severe cases it fails.

Treatment by blood transfusion or the more radical "exsanguination-transfusion" was tried at the hospital in seven cases. The latter operation is carried out as follows: Blood is withdrawn from the patient until he shows signs of the loss. In infants it may be withdrawn through the fontanelle from the longitudinal sinus. In older children the external jugular or femoral vein or radial artery may be used. It is impossible to obtain much blood from the superficial veins of a child under 5, particularly if the circulation is sluggish. Transfusion is then commenced through the great saphenous vein over the internal malleolus while further exsanguination is being carried out. In an infant only a small amount of blood (up to 120 c.cm.) can be withdrawn before transfusion is begun. But it seems that sufficient blood can be withdrawn until so much toxin is removed as will turn the scales in the patient's favour. The transfusion is carried out preferably with citrated blood. Out of seven cases of severe toxic shock from cases of superficial burns showing symptoms which used to be considered fatal at the hospital, five terminated in recovery. The following is an example. A boy, aged 2½ years, was admitted. Six days before he had fallen into a tub of scalding water. He had been treated at home for second and third degree burns extending over the back from the lower angles of the scapulæ to the upper part of the thighs and forward to the mid-axillary line on each side. He was desperately ill and the extent and severity of the burn were such that the prognosis seemed hopeless. He was exceedingly restless and toxic. 360 c.cm. of blood were transfused immediately. He showed moderate improvement, but the temperature remained high. The restlessness increased and a severe convulsion occurred. Exsanguination (260 c.cm.) and transfusion (400 c.cm.) were performed. The general condition improved, but there was intermittent twitching of the arms and legs, for which mag. sulph. was given subcutaneously. *Steady improvement followed.* But the toxæmia again increased and the circulation failed. As a last resort blood transfusion (300 c.cm.) was performed. The temperature fell, the general condition improved, and recovery ensued.

Dr. Robertson found that examination of the blood and urine in these cases did not give any signs to indicate transfusion. He had to rely on the clinical

Manchester merits attention. At Croydon certain backward children were selected and taught in small classes in the hope that they would be able more or less to resume their normal place on the ladder of educational attainments. In Manchester much the same plan has been adopted, but younger children, who were being taught in Standard I. in neighbouring schools, were selected. The making of arrangements of this sort by an education authority might well be considered a practical measure and constitute in a large sense a medical solution of some of the difficulties in the education of the backward child.

A point which should receive consideration is whether, in certain more or less special circumstances, those children of weak general ability who are all round mentally inefficient, but not sufficiently deficient as to be classed as mentally deficient—the very "thickheads"—should not be taught in a special class, associated, it may be, with an ordinary public elementary school rather than in a special class for mental defectives. Children such as these would seem to require tuition of a different character from the mentally deteriorated. It is at present difficult to differentiate between the teaching these children should receive and that given to mentally defective children, but the formation of such a class might help to provide the proper training for the backward child, and also create valuable medico-psychological knowledge. The material for such classes can be found in any thickly populated centres.

Public Health in Egypt.

LIKE many other matters in Egypt, the health organisation of the country is at present undergoing a radical change. Progress must necessarily be slow, but that a beginning has been made is evident from a perusal of Lord ALLENBY's report as High Commissioner for 1920, the medical portions of which have been summarised in two recent issues of THE LANCET.[1] In accordance with the recommendations of the Commission, which sat under the presidency of Dr. ANDREW BALFOUR during the summer of 1918, the director-general of the Department of Public Health has now become an Under Secretary of State for Health, and so enjoys a far more influential position than formerly; the deputy-director has now become director-general; and a new post of inspector-general has been created to which, we learn with satisfaction, an experienced Egyptian has been appointed. These changes in the higher personnel no doubt augur well, but they must be regarded merely as a beginning, for the recommendations of the Balfour Commission cover every aspect of health administration throughout the country, and extend even to the village and the doings of such humble officials as sanitary barbers. When the scheme is complete, there will be a technical adviser and director of medical intelligence to assist the Under Secretary and the director-general; also directors of (1) Sanitary Services, (2) Epidemic Services, (3) Medical Services, (4) Lunacy, (5) Medical Education, (6) Public Health Laboratories, and (7) Sanitary Engineering, and in addition a secretary-general who will control personnel, registration of vital statistics, and similar matters; all these officials to be responsible to the director-general. In this way it is hoped the directorate will be relieved of many trivial matters of detail.

A knowledge of Egypt and a study of Lord ALLENBY's report indicate that many preventable diseases still maintain their firm hold upon the country. It is a matter for congratulation that the reduction in the incidence of small-pox is as great as 60 per cent. when compared with the figures of the previous year, and from the fact that over ten million doses of vaccine lymph were prepared in the Vaccine Institute during 1920 against half that number in the previous 12 months, it is obvious that a systematised attempt is being made to reduce this scourge. There is apparently to be a general campaign against ankylostomiasis and schistosomiasis, and could these two diseases be appreciably reduced, the increased working capacity of the fellahin would amply repay the capital outlay. Pellagra as an equal drain on the energies of the labourer might well receive attention by those engaged in the attack on the two worm infections. These efforts on the part of the authorities, and many similar ones which are dealt with in the report, read excellently on paper, but as long as the success of their execution depends entirely on administrative reforms, very little improvement is likely to result in the health and happiness of the toiler in the fields, upon the value of whose work the prosperity of Egypt rests. What is essential in addition to administrative reforms is an educational campaign and an attempt to convince the people of the country at large that the disabilities from which they suffer are mainly preventable, but only with the coöperation of every member of the community. Are there signs that such a campaign is in progress or contemplated?

A consideration of the health situation in the Soudan is full of interest. As in Egypt, so in the Soudan, small-pox has been of considerable importance of late. Malaria, on the other hand, stands out in far greater prominence than in Egypt, and a comparison of the diseases prevalent in the two countries shows that there are many striking differences in the relative importance of the various infections demanding attention. The desert has proved an effectual barrier between these two populous areas in the past, but improved communications and the migration of labour, necessitated by the present scheme of Soudan development, have resulted in a changed situation; there is likelihood that much disease will be spread from one country to the other unless adequate precautions are taken to prevent this. To meet the needs of the case, labourers passing from Egypt are now detained in a quarantine camp at Halfa, and there are medically examined, shaved, bathed, disinfected, and treated with a vermifuge. This is a step which appears to have been taken only just in time, and it is to be hoped that no slackness will be permitted in the execution of such measures in the future. Should the worm diseases of Egypt be allowed to spread and take as firm a hold on the population in the cotton-growing areas of the Soudan and exercise an influence as baneful as in Egypt, the authorities will be alone to blame. Another infection which it is essential to control is tuberculosis. The Soudanese show very little resistance to this disease, and when infected usually succumb; the spreader of infection exists for so short a time that little harm results, and the tubercle rate in the Soudan appears to be low. Egyptians, on the other hand, show a far higher resistance and, in consequence, chronic centres of the disease may be established in the Soudan should those infected be undetected and rejected at the frontier. Such an introduction of tubercle into the Soudan might prove as great a calamity as did the infection of the negro in the Southern States of America.

[1] THE LANCET, Dec. 3rd and 10th, pp. 1195 and 1254 respectively.

fennel fruit, chamomile flowers, senna leaves and fruits, and a number of bunion plasters. This moth is well known as a pest of flour and grain, being especially common in rice. In general appearance it resembles a clothes-moth, but it actually belongs to the group Pyralidina, of which the flour-moth, *Ephestia kühniella* Zeller, is also a member. *Corcyra cephalonica* was first described in 1865, having been found in some dried currants by Mr. Hind, of York. The name *Corcyra* was given to the moth because it was thought to have been imported from Corfu, where currants are cultivated. The moth is of Eastern origin, and was brought to Europe by the rice trade. *Ephestia kühniella* is a closely related species of similar general appearance, and was carried to Europe from America as a result of commerce in grain and meal. It was formerly erroneously known as the Mediterranean flour-moth. Its larva is stout in build and has a pinkish tint, while the larva of *Corcyra* is more slender and dull whitish in colour. A third moth, *Borkhausenia pseudospretella* Stt., belonging to the family Tineina, which includes also the common clothes-moth, was found a short time ago in large numbers in a specimen of valerian root, which had been partly reduced to powder by the ravages of its larva. This moth was introduced from America about the year 1840 and is now a common inhabitant of houses, feeding upon parts of plants, skins, seeds, and the like. All these moths show a complete metamorphosis, and in every case it is the larvæ with their strong biting jaws which attack the drugs, while the moths have suctorial mouths and are unable to feed upon hard materials. The most satisfactory method of exterminating these pests is the application of heat. A temperature of 60° C. (140° F.) maintained for 15 minutes will destroy eggs, caterpillars, and moths. When large bags of drug are being dealt with, it is necessary to ensure that the required temperature is reached at the centre of the bags, and this can be readily arranged by heating the store containing the bags by air driven over steam-pipes for a period of two or three days, as suggested by A. W. Knapp for the treatment of cocoa. Fumigation with carbon bisulphide vapour is moderately successful in getting rid of the moths, but does not so effectually destroy the eggs; in a trial experiment made upon a large scale, only 50 per cent. of the larvæ were killed. Other fumigating agents such as formaldehyde, carbon tetrachloride, and trichlorethylene have been tried with indifferent result. A knowledge of these things may save the contents of the doctor's drug store.

ARTIFICIAL PNEUMORACHIS IN MENINGEAL INFECTIONS.

AT a recent meeting of the American Neurological Association Dr. Edward Affleck Sharp,[1] of Buffalo, N.Y., remarked that injection of air or oxygen into the ventricles of the brain had become a recognised procedure in neurological and surgical diagnosis. Injection of air or oxygen into the subarachnoid space by lumbar puncture producing an artificial pneumorachis had also been found of value in the treatment of acute infection of the meninges. During an epidemic of meningococcus meningitis in 1916–1917 a few cases occurred in which the purulent fluid was obtained with difficulty owing to adhesions or blocking of the vertebral canal. Injections of half-strength normal saline diluted the fluid and broke down adhesions, permitting a free flow of the purulent fluid. In some of these cases oxygen was injected and an additional quantity of purulent fluid was evacuated before injection of antimeningococcal serum, the oxygen in such cases probably acting only as a mechanical agent in displacing the fluid and opening up secluded pockets of adhesions and not possessing any germicidal action. The average amount of oxygen introduced was from 10 to 15 c.cm. No bad effects have ever resulted from the oxygen injections. During the last four years Dr. Sharp had treated 64 cases by this method. Of these 30 were cases of meningococcus meningitis, of which 23 recovered and 7 died; 12 were cases of tuberculous meningitis, of whom 3 recovered and 9 died; 10 were cases of lethargic encephalitis, of whom 8 recovered and 2 died; 2 were cases of anterior poliomyelitis, which both recovered, and 10 were cases of pneumococcus, streptococcus, or typhoid meningitis, which were all fatal. Dr. Sharp points out that the mortality of 23 per cent. among the cases of meningococcus meningitis compares very favourably with the statistics of cases of meningococcus infection in which antimeningococcus serum alone was used, especially as the new method was confined to the severe and apparently unfavourable cases. The paper was illustrated by a skiagram showing that oxygen injected by lumbar puncture may reach the ventricles, spread over the cerebral cortex in the subarachnoid space, and fill the cisterna magna.

DENTAL REGISTRATION.

ANY dentist, or person who believes himself entitled to registration under the Dentists Act, 1921, who desires to know his rights and obligations under that statute, cannot do better than acquire Sir Kingsley Wood's small but comprehensive volume.[1] It does not, of course, explain or embody regulations not yet approved and which had not been even discussed by the Dental Board when it was written, but it explains clearly the Act so far as it goes and the effect of its sections. It includes a brief survey of the Dentists Act of 1878, and contains the text of that statute as well as that of the new Act. The explanations given appear to be ample for their purpose at this stage, and should call the attention of those concerned to many points which otherwise might escape their notice. The knowledge of the law which, as British subjects, we are all assumed to possess does not always carry with it the power accurately to interpret the meaning of a Parliamentary draughtsman, or help us to follow his references to preceding legislation.

It has been pointed out to us that in a recent leading article upon the new Dental Board the references to the position of the Royal College of Surgeons of England are not accurate. The evolution of professional dentistry is a long story of which we could only give an abstract. A principal part was played by the Odontological Society when representations brought about the granting of a charter, but the charter was not granted to the Society, but to the Royal College of Surgeons, empowering the College to institute a Department in Dental Surgery.

THE Trustees of the Beit Memorial Fellowships for Medical Research have elected the following candidates to Fellowships of the annual value of £400:—

Mr. Robert Keith Cannan, M.Sc., for research into some chemical aspects of metabolism and digestion, at University College, London.

Mr. Herbert Davenport Kay, B.Sc., for research into the degradation of carbohydrates and allied substances by micro-organisms, at the Lister Institute.

Dr. Mary Kathleen Forsaith Lander, for research on the evolutionary process of development of stereoscopic vision and conjugate movements of the eye, at University College, London.

Dr. Harry Goldblatt, for research on the quantitative relation of fat-soluble A deficiency to the development of experimental rickets, and on the effect of parathyroidectomy on immunity, at the Lister Institute.

Dr. Louis Gross, for research on intestinal stasis, at the Royal College of Surgeons and London Zoological Gardens.

Dr. Ethel Marjorie Luce, for research on accessory food factors, with special reference to the relationship of ductless glands to calcium metabolism, at the Lister Institute.

Prof. T. R. Elliott, F.R.S., has been appointed a member of the Advisory Board.

---

[1] Dental Registration, being a Practical Guide to the New Dentists Act, by Sir Kingsley Wood, M.P., a Solicitor of the Supreme Court, Honoursman and John Mackrell Prizeman, Law Society. London: Baillière, Tindall and Cox. 1921. Pp. 136. 5*s.*

cause a Consumption happen to get into their Bodies they may likewise be quickly forc'd out again, through some of the *Emunctories*, before they are produc'd into Life; or else be wholly destroy'd."

A hundred and fifty-seven years later Louis Pasteur laid again the foundation-stone of that castle which his forgotten predecessor had so surely and deftly constructed, if only in the air. Sound as is our principle of "no acceptance without verification," it may yet be permitted to wonder how much suffering might have been prevented in those years, if Benjamin Marten's contemporaries had been willing to accept his theory and wait awhile for the verification which was in their time impossible.

THE ERADICATION OF TUBERCULOSIS IN CATTLE.

AUSTRALIA is the latest convert to a scheme initiated by the Bureau of Animal Industry in U.S.A. and since adopted in Canada for dealing with tuberculosis in cattle. A memorandum from Col. J. A. Gilruth, D.V.Sc., administrator of the northern territory of Australia, explains the accredited herd system, the aim of which is first to get rid of tuberculosis in a pure-bred herd of cattle, and when this has been done to give the owner the advantage of having his herd placed on an official list of tuberculosis-free herds. A herd is declared to be free from tuberculosis when no animal is found to be tuberculous after two annual or three semi-annual tuberculin tests and after thorough physical examination. The subcutaneous test with tuberculin is the one generally practised, but it may be supplemented by the ophthalmic test with tuberculin and the intra-dermal test. There is some evidence to show that the latter method is apparently gaining ground and may in time supersede the subcutaneous test. It is claimed that it relieves the inspector of the drudgery of prolonged observation of temperature. The intra-dermal test causes a reaction in diseased animals, even where repeated subcutaneous injections of tuberculin at short intervals has made them unresponsive to the subcutaneous test; moreover, it can be applied frequently to the same animal without producing immunity to tuberculin. Under this accredited herd system, any animal to be slaughtered is first valued and suitable compensation is awarded. The list of certified tuberculosis-free herds continues to grow in the United States, and from a recent communication from Dr. Frederick Torrance, D.V.Sc., the Veterinary Director-General of Canada, we learn that the system is making good progress also in the Dominion. This country lags behind. The Tuberculosis of Animals Order did good work while it was in operation, but has been suspended since 1914. It is time our authorities gave their attention to its revival or to some alternative scheme such as the one outlined.

SERUM-GLOBULIN AND THE WASSERMANN TEST.

IT has been known for some time that the substances concerned in the various immunity reactions are not found evenly distributed through the sera in which they occur, but that when these sera are split into different fractions the bodies in question are found in conjunction mainly with one or other of them. The same fact applies to antitoxins, and can be utilised in concentrating the total quantity present in a large bulk of serum down to a dose which can be administered without the inconveniences which attach to the making of a large injection. A number of experiments on these lines have been undertaken by various workers in an attempt to throw light upon the Wassermann reaction. Interest in this has been recently revived by the advocacy of the precipitation tests, such as that of Sachs and Georgi, which, it is thought, may give an indication of a syphilitic infection as reliable as the Wassermann reaction and much simpler of performance. Such tests consist in the production of a visible precipitate in the positively reacting sera by various and rather divers agents; a change suggestive of an alteration in the most readily precipitable constituent of serum—the globulins. Kapsenberg,[1] in a recent number of the *Annales* of the Pasteur Institute, has undertaken a reinvestigation of this subject, and confirms the fact that the active substance concerned in the Wassermann test resides in the globulin fraction of the serum. He finds that only when separation of the albumin and globulins is produced by salting-out is the whole of the active substance obtained in the latter fraction; where other methods of separation are employed the substance occurs in both fractions, although chiefly in the globulins. This is probably explicable on the grounds that the process of salting-out produces the most complete separation of these two fractions of the serum, whilst the other methods employed leave considerable traces of globulin in the albumin fraction. These facts being accepted, the further problem arises as to whether the positive reaction in syphilitic sera is due to a mere increase in the quantity of globulin present, or to some alteration in it; closely allied to the last possibility would be the presence of a new and foreign element in the serum, the result of the infective process, which becomes attached, possibly by adsorption, to the globulin at the moment of precipitation, without being an essential part and parcel of it. Noguchi and others claim that there is an actual increase in the amount of globulin present in syphilitic sera, a fact which is not confirmed by Kapsenberg. The treatment of the sera with substances presenting a large and active adsorbing surface has not resulted, in any case, in the diminution of the intensity of the Wassermann reaction, and from this the author inclines to the view that the active substance is an integral part of the globulin molecule; that the latter has suffered a change in the disease, and not that the active body is merely adsorbed by the precipitated globulin; which presumption is supported by the observation already referred to, that anything short of complete precipitation of the globulins fails to remove the active substance from the solution. In the Wassermann test the altered globulins are more readily precipitated from solution than are those of normal sera. In the presence of the lipoid antigens now in use they give rise to precipitates, presenting in the nascent state a surface suitable for the adsorption of complement, which thus disappears from the mixture, and a positive reaction results.

ARTHRITIS DEFORMANS OF THE HIP.

IN a paper calculated to upset several time-honoured conceptions with regard to arthritis deformans of the hip, or malum coxæ senile, Prof. Karl Petrén,[2] of Lund in Sweden, bases his discussion on a study of 103 cases observed at his hospital between 1910 and 1920. A scrutiny of these cases, in which the arthritis was confined to the hip, showed among other things that the title malum coxæ senile is misleading. In 8 per cent. the disease had appeared before the age of 40, and only in 13 per cent. had it appeared after 65—an age which Prof. Petrén refuses to associate with senility. Another conclusion to which he comes is that the disease is seldom, if ever, unilateral provided sufficient time has been allowed for it to develop in the second hip. In 61 cases the bilateral character of the disease was demonstrated both by ordinary physical examination and by the X rays. In several other cases one or other of these methods proved the disease to be bilateral, and only in 13 cases did it appear to be unilateral. Closer study of 10

[2] Acta. Med. Scand., 1921, vol. lv., fasc. iii.

Probably it would be extremely remote. Further, long experience of port health work and careful study of the literature of plague outbreaks go to show that the picture drawn above represents what actually occurs on some considerable scale throughout the world.

Wherever there is trade in grain from infected ports plague almost invariably follows sooner or later. In the reign of Justinian the disease was carried from Egypt to Byzantium by grain-ships. The same forces are still at work to-day. The more we know of the epidemiology of plague the easier is it to see how slight may be the chances of detecting its presence. It may be held, therefore, that all ships carrying grain, or those in whose cargo food forms a large part, should be Claytonised whenever the ship is empty. For a grain-ship to carry rats is a danger to the world.

THE INTERNATIONAL STANDARDISATION OF SERA:

AN IMPORTANT CONFERENCE.

A CONFERENCE was opened by permission of the Government at the Ministry of Health on Monday, Dec. 12th, at which the Health Committee of the League of Nations discussed the international standardisation of sera. The Conference, the personnel of which we gave last week, had not arrived at any conclusions in time to allow their publication. The conclusions of the various sub-committees were received in plenary Congress on Wednesday, Dec. 14th, and their reports on the international standardisation of sera in connexion with diphtheria and tetanus, meningococcus and pneumococcus, dysentery, and syphilis are appended.

THE RECOMMENDATIONS OF THE SUB-COMMITTEES.

I.—*Sub-Committee for Anti-Diphtheritic and Anti-Tetanic Serum.*

(Chairman : Dr. Louis Martin.)

The Committee for investigating methods for testing the potency of anti-diphtheritic and anti-tetanic serum considers it both possible and desirable to fix for both these sera an antitoxin unit which could be generally accepted and acknowledged as an International Unit.

Diphtheria Antitoxin.—Two units are used at present :—

(*a*) The German, determined in the Frankfort Institute for Experimental Medicine following the Ehrlich method with standard serum, and

(*b*) The unit determined in the Public Health Bureau at Washington.

Between these two units, according to the experiments carried out to date, there are only very small differences. To determine these differences accurately the standard sera and test-toxins for the necessary researches will be given to the various participating institutes both by the Frankfort Institute for Experimental Medicine and the Washington Public Health Bureau.

The result of the experiments performed with these sera and toxins at the several laboratories represented will be delivered on completion to the Danish State Serum Institute, which for this purpose will act as the central laboratory.

Tetanus.—Four methods at present are employed to describe the potency of anti-tetanic toxin. These four methods start from different points of departure and experiments have not yet determined the exact relation between the units determined by each of these methods.

The Committee consider, however, that it is desirable and possible to establish a common measure by an agreement on a single standard antitoxin, using the principle which has been adopted in connexion with the standardisation of anti-diphtheritic serum.

In the first instance the participating laboratories must fix experimentally the relations which obtain between the four units at present employed.

With this object an exchange of sera and toxins will be made in order to secure the necessary comparative experiments. The details of the experiments made with each method will in all cases be described in precise detail. All the relative documents will be sent to the Danish State Serum Institute which for this purpose will act as the central laboratory and the results will be discussed at a subsequent conference.

II.—*Sub-Committee for Antimeningococcus and Antipneumococcus Serum.*

(Chairman : Dr. Dopter.)

(*a*) *Antimeningococcus Serum.*—The Sub-Committee have unanimouly agreed as follows :—

1. With the object of obtaining full information regarding the various types of meningococci, the several laboratories mutually agree to exchange agglutinating serums and strains of meningococci, the latter being obtained exclusively from the cerebro-spinal fluid of meningitis cases.

2. Macroscopic methods will be employed in agglutination investigations, the bacterial emulsions having been kept for 24 hours at a temperature of 37° C., without prejudice to other methods which may also be employed. Investigations into the saturation of agglutinins may be carried out by any method.

3. In the existing state of our knowledge and without prejudice to the opinions of the several institutes participating in these researches and who are not represented at this conference it appears to be difficult to determine the therapeutic value of antimeningococcus serum by measurement of agglutinins, sensitisers (sensibilisatrices), and opsonins.

4. Fresh experiments will be undertaken in the various laboratories regarding the value to be attached to the determinations of antiendotoxic and bactericidal power.

(*b*) *Antipneumococcus Serum.*—The Sub-Committee have unanimously arrived at the following conclusions :—

1. A mutual exchange of cultures of different strains of pneumococci will be effected in the same manner as agreed upon in the case of meningococci.

2. Researches into the agglutinating power of antipneumococcus serum is of no value in determining its therapeutic power. The best method of titrating the serum is the measurement of the bacteriacidal power in animals, preferably mice.

3. New investigations will be carried out with regard to (*a*), the best method of inoculation—peritoneal or subcutaneous—for the titration of serum ; (*b*) the selection of methods, preventive or simultaneous, for the injection of serums and cultures ; (*c*) the monovalence or polyvalence of the different serums.

III.—*Resolutions Adopted by the Committee on Dysentery Serum.*

(Chairman : Prof. Kolle.)

1. It was agreed that it would be advisable that the different institutes, laboratories, &c., should exchange samples of serum and toxin and that further experiments should be carried out, using for these—
   (*a*) Different methods of titration,
   (*b*) Different species of animals.

2. In testing the potency of sera, there was a general agreement that the antitoxin, especially the antiendotoxin, should be estimated, and there was general agreement that this could be accurately carried out equally well with dead bacilli as with toxin. In reference to the method of testing the dysentery serum on mice, it was recommended that a series of tests should be carried out with the standard serum which the Frankfort Institute would supply, comparing them with methods in use in the various institutes, and that a report on these experiments should be presented at the next Conference. But it was considered that it was advisable also to test the anti-microbic power of serum, employing living bacilli for the test.

3. It was unanimously agreed that in the preparation of experimental anti-Shiga serum, the horses should be inoculated with the *B. dysenteriæ* (Shiga) only.

4. It was agreed that the question of the preparation and the standardisation of sera prepared from various other atoxic dysentery bacilli should not be discussed, as the actual state of our knowledge does not permit us to solve the question in a decisive manner.

IV.—*Sub-Committee on the Sero-diagnosis of Syphilis.*

(Chairman : Prof. Bulloch.)

The recommendations of the Committee appointed to discuss this question are :—

1. In a certain number of institutes the Wassermann reaction as practised in them should be compared with the methods of Sachs-Georgi, Meinicke and Dreyer-Ward (" Sigma ").

2. The number of cases examined in each institute should be 1000 of undoubted syphilis, and 1000 in which syphilis could be excluded as far as possible.

3. It is also recommended that the different methods should be compared on about (one and the same) 50 cases out of the 1000, at different stages of the disease. These repetition tests should be carried out on at least three or four occasions in the course of the disease, and it is recommended that the 50 cases should comprise especially suspected syphilis of the nervous system and of the eye.

points, such as rising temperature and general evidence of increasing toxæmia. A convulsion was a certain indication, but unfortunately a late one. It would be safer not to wait for this. His experience is that if burns are severe enough to cause a convulsion in a child under the age of 2 years it is rare for recovery to take place under any other method of treatment.

SEXUAL REFORM.

THE fact that everyone has, not only sex, but an unequalled knowledge of sexual life in his own person, may account for the sciolism and cocksureness of many popular deliverances upon this topic. Whatever the reason may be for this regrettable tendency, an excellent antidote may be found in the report of the first International Congress for Sexual Reform upon a scientific basis, held recently in Berlin, with an attendance at some sessions of over a thousand. Delegates were present from Italy, Russia, Sweden, Finland, South America, Holland, and other countries, whilst a congratulatory message was read from a French colleague. At this congress the older metaphysical outlook upon sex showed up in contrast with the newer physical outlook, while the conception of original sin gave place to that of congenital defect. The ancient idea—recently emerging from temporary obscuration—that the significance of sexual love does not end with its biological consequence of reproduction, but that it is a pre-condition of mental and physical life harmony, received emphasis. While admitting that permanent monogamous union had been evolved by the constructive force of Western civilisation, it was held by a section of the congress not to be well suited to eugenic ends, and its eventual modification, under safeguards, to a form eugenically more appropriate was discussed. The hindrances in the way of making people moral by Act of Parliament are certainly enhanced by the likelihood that the primitive sex impulse will always find itself in some measure opposed to current legislation. The difficulties besetting birth control were frankly recognised. Limitation of proletarian fertility would be difficult to effect, even by de-penalising abortion; a better means of meeting the disadvantages might be to enact that childless couples should bequeath a part of their property to the State. The desirability of legalising the interruption of pregnancy within the first three months was considered, but the neo-Malthusian method of prevention, rather than interruption, of pregnancy, was recognised as preferable. Sterilisation of degenerate criminals and lunatics was held to be advisable, at all events as a temporary measure.

Other thoughts which were current at the congress may be thus summarised. Sexual pædagogy should entail reform of education, with strict regard to formation of character, moral autonomy, and the sense of responsibility. Extremes are to be avoided. There must be no Thelemite laissez-faire, no blinking of juvenile sexual proclivities, no blind following of Freud. Puberty in boys hindered intellectual development, but in girls furthered it. A worker from the Berlin Institute of Sexual Science described "schizoid" types of human constitution, marked by inconstant sexual characters, verging even on asexuality, and often coinciding with somatic or endocritic stigmata like those found with true sexual inversion. There was in these types some approach to a schizophrenic psychosis, which, as Freud had shown, generally betrayed a conflict for survival between latent sexual desires and the collective psychical personality as moulded by its environment. The report of the congress is valuable as containing recent verdicts on Steinach's well-known work. Objection was taken to attributing the source of sexual hormones to the interstitial cells of the primary reproductive glands, and not to the endocrine system as a whole. It was stated that the amphibia had no interstitial tissue in ovary or testis, and yet showed well-marked secondary sexual characters. Notes were submitted of 37 patients, vasectomised more than a year previously with the object of rejuvenation, all of whom showed improvement in that respect without injury to their general health. On the other hand, castration followed by testicular implantation, in order to remedy inverted sexual desire, had uniformly failed. It seemed as though after puberty sexual aim became fixed in the central nervous system, although an alternative explanation of ill-success might be found in the extreme rarity with which organs implanted into human beings retained their vital activity. The congress, as was to be expected, held widely variant opinions, some of them obviously devoid of balance, and it can hardly be doubted that the atmosphere of public discussion will have exerted a useful check on extreme views. In this connexion it may be mentioned that the monthly journal of the Malthusian League, after appearing for 45 years as the *Malthusian*, is to be widened in scope, and to reappear in the New Year as the *New Generation*. The next congress will be held at Rome.

VINCENT'S DISEASE.

VINCENT'S disease, a comprehensive term including all the localisations of the fuso-spirillar symbiosis, forms the subject of a review in the December number of *Medical Science* by Dr. J. D. Rolleston, who quotes several recent articles showing that the disease has been unusually prevalent in Germany since the war. No satisfactory explanation of this occurrence has yet been offered, for while some writers attribute it to under-nourishment and a general declining of personal cleanliness due to lack of soap and heating material, others note its predilection for vigorous young persons of both sexes, and also point out that it did not become prevalent until 1919, when the supply of food was much more plentiful and richer in vitamins than during the last years of the war. Among the unusual localisations of the fuso-spirillar symbiosis reported by recent writers, reference is made in the review to the cases of infection of the thumb recorded by Hennessy and Fletcher in THE LANCET,[1] auto-inoculation of the skin of the anal region described by Koslowsky, infection of the external auditory meatus and middle ear related by various British otologists, and lastly an example of ulcerative and gangrenous balano-posthitis. The coexistence of Vincent's angina with syphilis or diphtheria is discussed, in reference to a case reported by Souchet in which the clinical and bacteriological appearances were those of Vincent's angina; here it was not until the development of a cutaneous eruption that the suspicion of syphilis arose and was confirmed by the presence of the *Spirochæta pallida* and a positive Wassermann reaction. Dr. Rolleston suggests that such complications as renal disease, myocardial changes, and peripheral palsies, which Reiche describes in his cases of Vincent's angina, were probably due to a coexistent diphtheria having been overlooked. Various topical applications for Vincent's disease, such as trypaflavin in the form of a ½ per cent. spray, a 10 per cent. solution of salicylic acid in equal parts of alcohol and glycerine, or pyoktanin in 1 per cent. solution have recently been recommended, but most writers still favour preparations of salvarsan such as neosalvarsan or silver-salvarsan for local application or intravenous injection.

MOTHS AS PESTS IN THE PHARMACY.

FROM time to time stocks of drugs become infested by animal pests such as mites, beetles, ants, and moths. The harm done by moths in particular was the subject of a paper read on Dec. 14th before the Pharmaceutical Society of Great Britain by Mr. T. E. Wallis, B.Sc., F.I.C., lecturer in botany. Recently the larvæ of the pyralid moth *Corcyra cephalonica* Stt. were found attacking many of the dry goods in a pharmacy at Hastings. The maggots showed themselves catholic in their tastes and had eaten starch, poppy-heads, whole and crushed linseed, ordinary distribution was £190,000, apart from the emergency distribution of £250,000 made by the Fund in July, 1920, out of its accumulated funds, and the special distribution of £250,000, which was generously entrusted to the Fund by the British Red Cross Society and the Order of St. John of Jerusalem for distribution on their behalf in aid of schemes of extension or improvement at hospitals able and willing to treat ex-Service men. The number of hospitals applying was 110, as against 108 in 1920.

---

[1] THE LANCET, 192

The report dealt at some length with the findings of Lord Cave's Committee and the duties which fell upon the Distribution Committee when King Edward's Hospital Fund was constituted the Voluntary Hospitals Committee for London. The Distribution Committee held a series of special meetings with the object of making specific recommendations to the Voluntary Hospitals Commission, and, as a result, grants were made to 24 hospitals which were in imminent danger of closing down. The Distribution Committee notified the hospitals that grants in aid of capital expenditure would have to be severely limited, but as a set-off total grants to maintenance were considerably increased.

The committee recommend that the following grants, made in past years in aid of schemes of building expenditure, should be renewed under the two years' rule: City of London Hospital for Diseases of the Chest, £500 to improvements; General Lying-in Hospital, £3000 to rebuilding on new site; Royal Northern Hospital, £2500 to new nurses' home; London Lock Hospital, £4500 to reconstruction of the Harrow-road Hospital, of which £3000 to be available for out-patient department; Queen Charlotte's Lying-in Hospital, £3100 to new out-patient department and other improvements; Queen Mary's Hospital for the East End, £1625 to improvements; Queen's Hospital for Children, £2538 12*s.* 11*d.* to improved out-patient accommodation; St. Mary's Hospital for Women and Children, Plaistow, £5500 to new nurses' home and out-patient department; St. Monica's Hospital, £100 to improvements; St. Peter's Hospital for Stone, £200 to improvements; St. Thomas's Hospital, £2500 to extension of nurses' dining-room; Victoria Hospital, £450 to new heating apparatus, transferred to extension of out-patient department and resident medical officers' quarters; West London Hospital, £4000 to improvements; Woolwich and District War Memorial Hospital Building Fund, £5300 to new general hospital.

The grants recommended by the Distribution Committee were presented by Sir FREDERICK FRY (hon. sec.) as follows:—

List of Awards.[1]

Acton Hospital	£110
Beckenham Cottage Hospital	55
Belgrave Hospital for Children	1200
Blackheath and Charlton Hospital (£25 of the grant to improved kitchen accommodation)	175
Bolingbroke Hospital	500
British Hospital for Mothers and Babies, Woolwich (£1000 of the grant towards the building of the amalgamated hospital, in accordance with the scheme submitted to the Fund)	1150
Canning Town Women's Settlement Hospital (£100 of the grant to reduce debt)	650
Central London Ophthalmic Hospital	400
Central London Throat and Ear Hospital (£250 of the grant to recent improvements in nurses' accommodation)	350
Charing Cross Hospital	4350
Chelsea Hospital for Women	550
Cheyne Hospital for Children	160
City of London Hospital for Diseases of the Chest, Victoria Park	3000
City of London Maternity Hospital	775
Clapham Maternity Hospital	300
Dreadnought Hospital, Seamen's (the amount of the grant this year is being generously given by King George's Fund for Sailors, as a temporary measure, earmarked for the Seamen's Dreadnought Hospital)	5000
East End Mothers' Lying-in Home (£50 of the grant to additional nurses' accommodation)	650
East Ham Hospital	£50
East London Hospital for Children	3000
Elizabeth Garrett Anderson Hospital	1000
Eltham and Mottingham Cottage Hospital	80
Evelina Hospital	1000
Finchley Cottage Hospital (£250 of the grant to extension, in accordance with the scheme submitted to the Fund)	350
Florence Nightingale Hospital for Gentlewomen (£100 of the grant to reduce debt)	325
French Hospital	200
General Lying in Hospital	550
German Hospital	—
Grosvenor Hospital for Women	775
Guy's Hospital (£500 of the grant to improvements in nurses' accommodation, in accordance with the scheme submitted to the Fund)	12,500
Hampstead General and North-West London Hospital	2750
Hendon Cottage Hospital	225
Hornsey Cottage Hospital	100
Hospital for Consumption, Brompton, including Sanatorium at Frimley	2000
Hospital for Diseases of the Throat	150
Hospital for Epilepsy and Paralysis	1750
Hospital for Sick Children (£100 of the grant to additional nurses' accommodation, in accordance with the scheme submitted to the Fund)	4900
Hospital for Women, Soho-square	1000
Hospital of St. John and St. Elizabeth	750
Infants' Hospital (£250 of the grant to reduce debt)	759
Italian Hospital	350
Kensington and Fulham General Hospital	30
Kensington Dispensary and Children's Hospital	30
King Edward Memorial Hospital, Ealing	575
King's College Hospital	7750
London Fever Hospital	250
London Homœopathic Hospital (£250 of the grant to reduce debt)	1500
London Hospital (£1000 of the grant to deficit on new nurses' home, in accordance with the scheme submitted to the Fund)	14,250
London Lock Hospital (£700 of the grant to maintenance of Harrow-road Hospital, and £50 to maintenance of Dean-street Hospital)	750
London Temperance Hospital	2200
Maternity Charity and District Nurses' Home, Plaistow (£500 of the grant to rebuilding and extension, in accordance with the scheme submitted to the Fund)	800
Metropolitan Ear, Nose and Throat Hospital	30
Metropolitan Hospital (£1000 of the grant to reduce debt)	4600
Middlesex Hospital (£250 of the grant to improvements to operating theatre)	7850
Middlesex Hospital Cancer Charity	850
Mildmay Memorial Hospital	525
Mildmay Mission Hospital	975
Miller General Hospital for South-East London	3500
Mothers' Hospital of the Salvation Army	750
National Hospital for Diseases of the Heart	500
National Hospital for the Paralysed and Epileptic (£2000 of the grant to reduce debt)	4750
Nelson Hospital, South Wimbledon (£400 of the grant to extension, in accordance with the scheme submitted to the Fund)	850
Northcourt Hospital and Home for Sick Children, Hampstead (grant given in consideration of the fact that curable cases are admitted)	50
Norwood Cottage Hospital	500
Paddington Green Children's Hospital	850
Passmore Edwards Hospital for Wood Green, &c.	75
Poplar Hospital for Accidents	100
Prince of Wales's General Hospital (£2000 of the grant to reduce general fund debt)	5000
Queen Charlotte's Lying-in Hospital	750
Queen Mary's Hospital for the East End (£750 of the grant to new maternity block, in accordance with the scheme submitted to the Fund)	5250
Queen's Hospital for Children	3500
Roll of Honour Hospital for Children	50
Royal Dental Hospital of London	250
Royal Eye Hospital	700
Royal Free Hospital	4250
Royal Hospital, Richmond	550
Royal London Ophthalmic Hospital (£500 of the grant to reduce debt)	3500
Royal National Orthopædic Hospital (£500 of the grant to reduce debt)	2350
Royal Northern Hospital, with which is amalgamated the Royal Chest Hospital, City-road	6800
Royal Waterloo Hospital for Children and Women	2350
Royal Westminster Ophthalmic Hospital	400
St. Andrew's Hospital, Dollis Hill	200
St. Bartholomew's Hospital	8700
St. Columba's Hospital	300
St. George's Hospital	7000
St. John's Hospital, Lewisham	500
St. John's Hospital for Diseases of the Skin	250
St. Luke's Hospital for Advanced Cases (£350 of the grant to acquisition of new premises, and their adaptation in accordance with scheme to be submitted to the Fund)	525
St. Mark's Hospital	200
St. Mary's Hospital (£500 of the grant to improvements to nurses' accommodation and operating theatre, in accordance with the schemes submitted to the Fund)	5500
St. Mary's Hospital for Women and Children, Plaistow	1350
St. Monica's Home Hospital	150
St. Peter's Hospital for Stone	150
St. Saviour's Hospital for Ladies of Limited Means, Osnaburgh-street	150

---

[1] The Distribution Committee draw attention to the fact that it must not be assumed that the reduction or absence of a grant implies dissatisfaction.

PLAGUE ON BOARD SHIP.

BY W. W. CLEMESHA, C.I.E., M.D., D.P.H.,
LIEUTENANT-COLONEL, I.M.S. (RET.)

THERE is no necessity to apologise for bringing this very important subject again before readers. Recent outbreaks of plague in many parts of the world are in all probability re-importations of the disease caused by infected ships' rats. The reason for this re-importation is probably to be found in the general lack of vigilance due to reduced staff, which was a necessary result of the war. Dr. W. M. Willoughby, Port Health Officer of London, has published several papers on the subject of plague epidemics in ships that have come under his cognisance; an exhaustive account of the outbreaks on shipboard that have occurred since the year 1896 appears in a report by Dr. R. J. Reece, of the Ministry of Health. During the years 1917–20 Dr. Willoughby reports that eight plague-infested vessels were seen by him in London; as a result of very careful inquiry he came to the important conclusion that, as a general rule, the earliest case amongst human beings on an infected ship is the storekeeper, whose business it is to issue rations for the ship's company. Out of 1715 persons exposed to infection on eight infected vessels 30 developed plague; no less than eight of these occurred amongst storekeepers and their assistants. Dr. Reece says, "the storekeeper who gets up the food for the native crew and the saloon steward who carries the food from the galley to the saloon are specially liable to infection." The cause for this state of affairs is, as suggested by these writers, that ships' rats require both food and water, and in search of these necessities they invade the store-room, and not infrequently the lavatories of the ship. Early cases amongst lavatory attendants have also been reported.

Eight plague-infected ships in a matter of four years may not seem a great number in so large a Port as London, but the all-important question suggests itself: If eight ships were discovered, how many were actually infected but escaped detection? In endeavouring to reply to this query, recent work on the epidemiology of plague will be of much assistance.

Difficulty Concerning Ships Apparently Healthy.

All who have had any experience of port health work will agree that it is only in regard to ships that have had cases of sickness or deaths amongst the crew that suspicion is at all likely to arise in the mind of ships' officers, who supply information to the visiting health officer. If rat mortality has occurred without human cases it might be noticed and reported, but an odd dead rat on a ship is no very uncommon sight, and very likely would escape notice or be forgotten. If no human cases occurred and no dead rats were found, the ship would be reported, in all good faith, as healthy; being classed as free from infection, unloading would take place at the wharf in the ordinary way. Possibly dead rats would be found on moving the cargo, but by that time the damage might be done and some infected rats have escaped ashore.

The "Plague Season."

Now it is well established that the fulminating epizoötic of plague in a rat-infested town in the tropics only takes place at a time when flea prevalence on the rats is at its height, and when climatic conditions give the maximum period of infectivity for the flea. These conditions constitute what may be called the "plague season"; when they are absent we get an entirely different type of outbreak amongst rats. It has been shown by Kunhardt and Chitre that if plague infection is brought into a rat community in the "off season"—that is, when the flea prevalence per rat is greatly reduced and the temperature is either too high or too low—only dropping cases occur amongst the rats, but the infection may be kept alive in this way months. Applying these facts to outbreaks on board one would expect to find both varieties amongst ships' rats. From Dr. Willoughby's figures it would appear that both types have been recorded; in two out of eight boats (the *Sardinia* and the *Clan Lamont*) no dead rats were found amongst the cargo—this would be very unlikely to occur in the explosive type of outbreak. Again, in Dr. Reece's valuable report we read, "There have been several instances that seem to indicate that the period during which rat plague may exist on board a vessel before its presence is discovered may be a long one." Then follows the details of the outbreaks of the ships *Highland Prince*, *Nankin*, and *Moora*. The complete facts of these outbreaks may well be studied in the report, but of the *Nankin* and *Moora* the author says, "It may be that infected rats concealed in merchandise found their way on board both vessels at Bombay and that the disease for some unexplained reason did not assume epidemic proportions among the rats for two months." Given certain conditions of flea prevalence, low temperature and humidity, a delayed epizoötic would result. This is the correct explanation of the remarkable course of events on these two ships. Unfortunately, there are no figures available showing the average number of fleas per rat in those captured or destroyed on board ship, but it may be held that there is doubt as to whether the flea prevalence on ships' rats is ever as great as it is on land. Obviously fleas must breed in the ship's hold, but it is very doubtful whether the conditions under which they live are as satisfactory as they are ashore. Flea prevalence fluctuates with climatic conditions even on land rats; the same must also apply to ships' rats. Many of the boats pass out of the tropics into colder climates three or four times in the year; this would certainly have a restraining influence. It is fair, therefore, to conclude that plague infection on shipboard does assume much the same phase as is known to exist in Indian villages in the "off season," and that in this state it is very likely to escape detection because the rat mortality is small and the chances of human infection much reduced.

The Small Freighter as a Rat Carrier.

Five out of eight of Dr. Willoughby's ships and at least 60 out of 100 of Dr. Reece's were big passenger vessels with voluminous and well-stocked food store-rooms. Frequently, there would not be much in the cargo that would prove attractive to rats as food, but a reference to the reports shows that occasionally these ships did carry grain. This brings us to the last point. Only a comparatively small proportion of the world's trade is carried in large passenger ships; the small freighter of 5000 to 10,000 tons is much more numerous, and is, therefore, a more important factor in the spreading of disease. Let us try to imagine the conditions on a vessel of this size carrying a cargo of grain. Grain coming from a plague-infected country like India in itself constitutes a grave source of danger. At this point I do not turn aside to discuss the whole question of the grain trade and its influence in the spread of plague; suffice it to say that the most recent work has shown that wherever there is a big grain trade, there plague constantly manifests itself. Broadly speaking, re-importation of the disease follows importation of foodstuff. In a boat of the type described, where the whole cargo provides food for rats, the necessity for them to have recourse to the crews' food-supply is considerably reduced; consequently the chances of infecting members of the crew would be lessened. Assuming that infection was brought on board at an inopportune moment, when the flea prevalence per rat was low and climatic conditions adverse, one might further amplify the picture by adding that the rats were the grey rat and the fleas *Xenopsylla astia* (vide the recent work by Cragg). The result would be a slow creeping outbreak of the endozoötic type, that would very likely pass unnoticed and might not cause any human cases. Under the circumstances described above what would be the chance of detecting the presence of infection on a ship?

On the motion of Lady AMPTHILL, seconded by Sir WILLIAM CHURCH, it was resolved that the cheques for the grants should be posted on Monday, Dec. 19th, except in the case of grants for the reservation of beds at consumption sanatoria during 1922, the cheques for which should be posted on Jan. 2nd.

The chairman of the King's Fund Policy Committee (Lord STUART OF WORTLEY), presented a report of that committee on the action taken by the King's Fund as Voluntary Hospitals Committee for London.

Viscount FINLAY then read letters from the King and from the Prince of Wales, expressing their interest in the efforts which were being made to re-establish voluntary hospital finance, and resolutions were passed with the object of re-organising the Fund on a basis better suited to deal with its new tasks. Among the aims of the Fund under the new organisation will be the establishment of a system of contributions from industrial sources and the raising from the general public of the large amount of fresh money which is required on the pound for pound principle to meet the conditions attached to the treasury grants. The following form the President's Powers Committee :—

General Council.—All the present members and the following new members : Col. Mildmay, Sir Cuthbert Wallace, and Major Wernher.

Management Committee.—Lord Stuart of Wortley, Chairman ; Lord Somerleyton, Vice-Chairman ; and the Chairmen of the other committees.

Finance Committee.—Lord Revelstoke, Chairman, Hon. N. Charles Rothschild, Hon. Algernon H. Mills, Sir John Craggs, Mr. Robert Fleming, Mr. M. C. Norman.

Distribution Committee.—Sir Cooper Perry, Chairman, Lord Somerleyton, Sir Francis H. Champneys, Bt., Sir J. Rose Bradford, Sir Cuthbert Wallace, Sir Frederick M. Fry, Sir Frederick Green, Mr. Yvon R. Eccles.

Revenue Committee.—Sir Alan G. Anderson, Chairman, Viscount Burnham, Lord Marshall, Hon. Sir Arthur Stanley, Col. Rt. Hon. Frank Mildmay, M.P., Sir William H. Bennett, Sir William J. Collins, Sir George Lawson Johnston, Sir Edward Penton, Prof. Winifred C. Cullis, Mr. Stuart de la Rue, Major Harold Wernher.

Hospital Economy Committee.—Mr. Leonard L. Cohen, Chairman, Hon. Oswald Partington, Lady Hall, Sir George Makins, Sir Owen Philipps, M.P., Sir James Kingston Fowler, Sir Basil E. Mayhew, Sir Walter Trower, Mr. John G. Griffiths, Dr. H. Morley Fletcher, Mr. Henry L. Hopkinson, Mr. Kenneth Prescott.

Subsequent to the meeting of the King's Hospital Fund a meeting of the League of Mercy was held at St. James's Palace on Dec. 19th, under the presidency of Princess Alice, Countess of Athlone, when it was stated that the actual amount collected by the League during the year was £34,000.

ROUMANIA.

(FROM OUR OWN CORRESPONDENT.)

Sterile Marriages and Examination of Spermal Fluid.

Dr. Achimescu has recently cautioned gynæcologists against the treatment of sterility on the assumption that the condition is always due to the woman. In every case, he believes, the husband should be questioned, and careful examination for spermatozoa should be made several times, at fairly long intervals, between which the subject should abstain from intercourse ; it is well known that a temporary azoöspermia occurs after repeated coitus. Dr. Achimescu has notes of 483 cases of sterility, in 58 of which he found absence of spermatozoa. In 19 of these cases the wives had been under treatment. Furthermore, he found in 37 instances persistent oligospermia, and in 13 instances necrospermia.

Indications for Surgical Sterilisation of Women.

Dr. Panuihescu, surgeon at the Bucharest University clinic, states that the performance of an operation which will render a woman sterile for life is never justifiable except to avoid a dangerous pregnancy, and that a condition that justifies abortion may not justify female castration. A contracted pelvis should not be considered an absolute indication for sterilisation, since with modern technique Cæsarean section has become a comparatively safe operation. Chronic nephritis may be considered an indication ; psychic and nervous conditions are a doubtful indication: insanity may be curable, and if it be severe asylum segregation would render sterilisation needless. In tuberculosis of the lungs abortion should be induced if there is hope for a cure ; in hopeless cases sterilisation is justifiable to avoid the strain of bearing and nursing a child. The most satisfactory method of operation is to remove the entire tube and close the superior angle of the uterus—the procedure advised by Chrobak at Vienna.

Consent to Operation.

Recent legal proceedings involving the question of consent to operation have attracted considerable attention in Roumanian medical and lay papers. One medical writer, in a careful review of the subject, states that the physician finds that he must in all cases either keep within the strict scope of the authority expressly given to him, or must so safeguard himself that he can prove by the testimony of reliable witnesses that he was asked to perform what operation he might find necessary, and that the operation actually performed was, in fact, necessary or desirable. There is some confusion as to the person from whom consent must be obtained ; it is, however, laid down as a general rule that this person is the husband in the case of an operation upon the wife, whilst for operations on children consent must be obtained from the parents, guardians, or other persons legally responsible for the care of the child.

Diarrhœa in Albania.

There is an alarming increase of gastro-intestinal disorders in Albania ; thousands of working men are unemployed, and are compelled to live on a semi-starvation diet. The sanitary conditions of the bakeries are very unsatisfactory ; the bread is bitter and made of inferior flour (maize) in a primitive manner. Another great source of gastro-intestinal disease is the enormous consumption of decayed vegetables, raw or in a half-cooked condition.

Measles Epidemic in Bessarabia.

Since the outbreak of measles three weeks ago the disease has spread rapidly ; its dissemination is held by health officials to be due to negligence on the part of parents in not calling in a physician to see that the affected children are properly isolated. The epidemic is most severe in the Kishinev district ; in that city all school-houses have been disinfected, and in addition the Bureau of Public Sanitation has disinfected the homes of many children. Last week 156 cases were reported to the district medical officer. The cases are all very mild, and recovery takes place almost without complication ; no fatal case has yet been reported.

"Club Rates" for Medical Services.

In a large town, Figulmares, a private sick club has attempted to exploit the medical men by underpaying them and by admitting members without regard to their financial status, so that wealthy families, who could easily pay regular medical fees, availed themselves of this form of cheap medical service. The local medical union has adopted a resolution to the effect that on and after Jan. 1st, 1922, no member of the union shall accept a post under the sick club, or continue to work at a rate less than the regular charges for services to patients not members of that club ; also that no physician shall attend families of the members of this club at a fee lower than the regular rate. Nothing in this resolution is to be construed as preventing any member from attending the worthy poor at a less rate, or giving free service to those who are too poor to pay anything. Any violation of this order will be considered unprofessional conduct, and it will be the duty of the censors to expel such members from the union, if proof of such conduct be presented to them.

Bucharest, Dec. 1st.

4. The worker should be allowed the opportunity of studying the respective authors' own methods in the respective institutes.

5. The places where the tests are to be carried out should be efficiently equipped, and the serologist should be in as close touch with the clinician as possible.

6. For the flocculation tests the serologist should use only those extracts prepared or controlled by their respective authors.

7. The samples of serum to be tested should be known only by numbers, and the serologist should not have access to the clinical or pathological records until the whole series of tests is concluded, but the chief of the laboratory may cause any serum to be retested without making the serologist aware of the fact.

8. A preliminary report to be submitted after the first 500 tests have been concluded.

9. All reports on tests should include information as to—

(a) Reliability of the method,
(b) Complexity of technique,
(c) Relative consumption of time by the method,
(d) Expense,
(e) Ease and accuracy with which the reaction can be observed,
(f) Percentage of dubious results,
(g) The extent to which the method yields quantitative results.

It is recommended that all the results should be finally submitted to the State Institute for Seropathy of Copenhagen.

A LUNCHEON TO THE DELEGATES.

On Wednesday Sir ALFRED MOND, the Minister of Health, presided at a luncheon given by the Government to the delegates to the Conference. The luncheon was held at the Carlton Hotel and the guests were grouped at separate tables, the occasion being a purely social one, at which the great work being done by the Health Committee of the League of Nations could be publicly recognised. There were but two speeches, one by the Minister of Health welcoming the company, and the other a reply by Prof. Madsen, the President of the Health Committee.

Sir ALFRED MOND said that he was particularly glad that the delegates to discuss matters of international health had not been drawn exclusively from the countries within the League of Nations, although the Conference was being held under the auspices of that League. He spoke eloquently of the part which medicine would necessarily play in the great work of reconstruction before the world.

Dr. MADSEN, in reply, disclosed certain of the conclusions which had been arrived at by the sub-committees, and considered that the results of the first conference had been very successful. Unanimous agreements had been arrived at with regard to certain important therapeutic sera, and machinery had been indicated by which comparative results could be obtained for further study. He made special reference to the valuable assistance which had been given by the British Ministry of Health to the work of the Health Committee of the League of Nations in placing at the disposal of the committee the services of the senior medical officer Dr. G. S. Buchanan as adviser, Dr. F. Norman White as chief epidemic commissioner, and Dr. E. J. Steegmann as secretary. Dr. Steegmann's appointment was a temporary one, and he has since been succeeded by Dr. Rajchman. Dr. Madsen also referred to the invaluable aid rendered in reference to the particular work in hand by the Medical Research Council. He spoke in fluent English.

The following guests were present:—

Sir T. Clifford Allbutt, Sir F. Andrewes.
Sir P. W. Bassett-Smith, Surgeon-General Rupert Blue, Sir A. Bowlby, Mr. L. G. Brock, Dr. G. S. Buchanan.
Sir Mackenzie Chalmers, Major-General Sir Havelock Charles, Dr. S. A. M. Copeman, Dr. Cotoni. Dr. F. J. H. Coutts.
Dr. H. H. Dale, Mr. J. Conway Davies, Lord Dawson of Penn, Prof. H. R. Dean, Dr. R. Doerr, Dr. Dopter, Captain S. R. Douglas, Prof. G. Dreyer.
Dr. A. Eastwood, Mr. F. W. Emett.
Sir Walter Fletcher.
Dr. M. H. Gordon, Mr. B. Gosio.
Dr. W. H. Hamer, Colonel L. W. Harrison, Dr. L. Hirszfeld.
Viscount Knutsford, Dr. W. Kolle.
Major-General Sir W. Leishman.
Dr. T. Madsen, Prof. C. J. Martin, Dr. Louis Martin, Dr. M. Miyajima, Sir Norman Moore, Dr. R. Mueller.
Sir George Newman, Colonel Perrin Norris.
Mr. R. A. O'Brien.
Dr. L. Rajchman, Dr. G. Renaux, Sir William A. Robinson.
Mr. H. Sachs, Prof. C. S. Sherrington, Sir Squire Sprigge, Colonel P. G. Stock.
Mr. Douglas Veale.
Dr. F. Norman White, Sir Dawson Williams, Sir G. Sims Woodhead.

It is understood that the Conference will meet again in six months' time, probably at the Pasteur Institute in Paris, to report progress and arrive at further recommendations for the organisation of international health matters. In the meantime the work of the sub-committees goes on.

KING EDWARD'S HOSPITAL FUND FOR LONDON.

A MEETING of the General Council of King Edward's Hospital Fund for London for the purpose of awarding grants was held on Dec. 14th, Viscount FINLAY (Member of the President's Powers Committee) being in the chair.

Lord REVELSTOKE, hon. treasurer, said that the amount received for general purposes to Dec. 3rd, 1921, was £221,326. This exceeded the total indicated in the estimate laid before the Council in November, the increase being due to the generous action of King George's Fund for Sailors in again providing the amount of the grant of £5000 to the Seamen's (Dreadnought) Hospital. The legacies received during the last 11 months amounted to £74,000, as against £18,000 in 1920, and the Council had decided to distribute a portion of these additional receipts, and to keep a portion in reserve, thus effecting a reasonable compromise between an endeavour to afford every possible assistance to the hospitals during this year, and an equal desire to maintain a regular distribution as a stabilising influence and element in their finance.

Lord REVELSTOKE then read the following communication from Lady Mount Stephen:—

"I have been allowed to tell you by the executors that my husband has left the residue of his fortune to King Edward's Hospital Fund. It is, I believe, practically nearly the whole of his fortune, for the legacies, &c., in proportion do not amount to anything of importance. Would you, as Treasurer of the King's Fund, make this known to the Council?"

Viscount FINLAY moved a resolution recording the deep regret of the General Council of the Fund at the death of Lord Mount Stephen, to whose benefactions the Fund and the sick poor of London owed so much. His gifts to the capital of the Fund during his lifetime amounted to some £500,000.

The resolution was seconded by the Governor of the Bank of England, put from the chair, and carried unanimously.

Sir WILLIAM COLLINS, in making the annual statement on behalf of the League of Mercy, said that so far as he could say the League would be in a position to make a contribution of £14,000, possibly more, making a total from its foundation of £323,034 to the voluntary hospitals of London through the King Edward's Fund, and, including extra Metropolitan hospitals, £360,429. The new scheme, originally suggested by Lady Hall, for collections from people in domestic service, had already brought in £200 or £300 during the current year, and they hoped great things of it.

Report of the Distribution Committee.

Sir COOPER PERRY (the chairman of the Distribution Committee) presented the report of that committee, which announced that the amount placed at the disposal of the Distribution Committee for allocation amongst hospitals at the present distribution was £210,000. The amount distributed last year at the

* Including membranous croup.

Battersea, 12·9 in Wandsworth, and 13·0 in Hampstead and in Camberwell, to 17·2 in Chelsea and in Bermondsey, 17·5 in Holborn, 17·6 in Kensington, 18·9 in Shoreditch, and 19·2 in Finsbury. The 6450 deaths from all causes included 427 which were referred to the principal infectious diseases; of these, 9 deaths resulted from enteric fever, 43 from measles, 35 from scarlet fever, 40 from whooping-cough, 165 from diphtheria, and 135 from diarrhœa and enteritis among children under 2 years of age. No death from any of these diseases was recorded in the City of London. Among the metropolitan boroughs the lowest death-rates from these diseases were recorded in Hammersmith, Chelsea, the City of Westminster, Holborn, Wandsworth, and Deptford; and the highest in Stepney, Poplar, Bermondsey, Greenwich, and Woolwich. The 9 fatal cases of enteric fever exceeded the average in the corresponding period of the five preceding years by 3; of these, 3 belonged to Camberwell and 2 to Kensington. The 43 deaths from measles were 22 fewer than the average; of these, 14 belonged to Poplar, 9 to St. Pancras, 5 to Lambeth, 4 to Stepney, and 3 to Southwark. The 35 fatal cases of scarlet fever were 20 in excess of the average; of these, 4 belonged to Fulham, and 3 to each of the boroughs of Hammersmith, Southwark, Lambeth, Wandsworth, and Lewisham. The 40 deaths from whooping-cough were 14 greater than the average; of these, 5 belonged to Poplar, 5 to Lambeth, 4 to Bermondsey, 4 to Battersea, 3 to Stepney, and 3 to Camberwell. The 165 fatal cases of diphtheria exceeded the average by 78; this disease was proportionally most fatal in Hampstead, Stoke Newington, Stepney, Greenwich, and Woolwich. The 135 deaths from infantile diarrhœa were 16 in excess of the average; the greatest proportional mortality from this disease occurred in St. Marylebone, Shoreditch, Bethnal Green, Bermondsey, and Greenwich. The aggregate mortality in London during November from these principal infectious diseases was 31 per cent. above the average.

The deaths from influenza registered in London during the five weeks ended Dec. 3rd numbered 91, against 9, 21, and 40 in the three preceding months, and 90, 31, 8676, 97, and 67 in the corresponding periods of the five preceding years.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surgn. Lieut. C. M. Williams has been promoted to the rank of Surgn. Lt.-Comdr.

ROYAL ARMY MEDICAL CORPS.

Lt.-Col. and Bt.-Col. M. H. G. Fell, C.B., C.M.G., is restored to the establishment.

Capt. E. G. S. Cane, D.S.O., relinquishes the temp. rank of Maj.

Temp. Capt. S. P. Snook relinquishes his commn. and retains the rank of Capt.

Temp. Capt. E. C. A. Smith relinquishes his commn. on appt. to the Ind. Med. Service.

TERRITORIAL ARMY.

Lt.-Col. (Bt. Col.) J. R. Kaye, having attained the age limit, is retired and retains his rank.

The undermentioned officers, having attained the age limit, are retired and retain their rank except where otherwise stated: *Lt.-Cols. E. M. Callender and J. Allison (with permission to wear their prescribed uniform), and P. C. Smith.* Majs. A. MacGillivray, J. Wilson, and W. W. Jones (with permission to wear their prescribed uniform), and A. Robertson. Capts. A. Baxter (granted the rank of Lt.-Col.), A. N. S. Carmichael, J. Wood, D. G. Kennard, and A. E. Ridsdale (granted the rank of Maj.), and R. A. Burditt, H. A. Beetham, H. W. Lance, J. S. Clarke, and F. G. Vicars.

Maj. R. C. Highet (Lt.-Col., ret., T.F.) reverts to the retired list and retains his rank, with permission to wear the prescribed uniform.

Officers relinquishing their commissions and retaining their ranks: Capts. P. H. G. Gosse, C. G. Brentnall, A. L. Bodley, J. Graham (granted the rank of Maj.), J. W. M. Jamieson, A. W. Sutherland.

1st Lond. (C. of L.) San. Co.: Lt. E. V. Suckling relinquishes his commission and retains his rank.

4th N. Genl. Hosp.: Maj. D. J. G. Watkins, having attained the age limit, is retired and retains the rank of Maj.

Willesden Hospital (£500 of the grant to extension as general hospital, in accordance with scheme to be submitted to the Fund)	1225
Wimbledon Hospital (£250 of the grant to new nurses' home, in accordance with the scheme submitted to the Fund)	425
Winifred House Invalid Children's Convalescent Hospital Home	25
Woolwich and Plumstead Cottage Hospital (see special grant below)	25
	£208,500

Special Grant.—Woolwich and District War Memorial Hospital Building Fund (to provision of general hospital, in accordance with the scheme submitted to the King's Fund) £1500

Summary.

Grants	£208,500
Special Grant	£1,500
Total grants to hospitals for the year 1921	£210,000

Mr. WHITTALL having seconded, the motion was carried unanimously.

Report of Convalescent Homes Committee.

Sir WILLIAM H. BENNETT (Chairman of the Convalescent Homes Committee) presented the report, which stated that the sum available for distribution amongst convalescent homes and consumption sanatoria was £10,000, the same amount as in 1920. The number of applications eligible for consideration amounted to 59 from convalescent homes and 10 from consumption sanatoria, as against 51 and 11 respectively last year.

The committee recommended that part of the amount available should be distributed in the form of grants to consumption sanatoria in consideration of the reservation of beds for the use of patients in London hospitals allocated as follows:—

Chest hospitals: 8 beds to the City of London Hospital for Diseases of the Chest; and 4 beds to the Royal Chest Hospital branch of the Royal Northern Hospital.

General hospitals: 2 beds to Charing Cross Hospital; 5 beds to Guy's Hospital; 2 beds to King's College Hospital; 7 beds to the London Hospital; 3 beds to the Middlesex Hospital; 2 beds to the Royal Free Hospital; 2 beds to St. George's Hospital; 1 bed to St. Mary's Hospital; 5 beds to St. Thomas's Hospital; 2 beds to University College Hospital; and 1 bed to Westminster Hospital.

For several years past the committee have recognised that the treatment of tuberculosis has been more and more regarded as coming within the scope of the public health authorities, either directly or as part of the National Insurance Scheme; and the committee have anticipated that a time would come when the Council might no longer feel justified in devoting part of its annual distribution to the provision of accommodation for London patients out of voluntary funds. The greatly increased needs of the London hospitals for maintenance grants have brought this question to a head rather earlier than the committee would have desired, but they feel that they have no option but to recommend that the practice of making grants to consumption sanatoria in consideration of the reservation of beds for patients in London hospitals should be discontinued after the present distribution.

List of Grants Recommended to Consumption Sanatoria and Convalescent Homes.

Sir ALAN ANDERSON (hon. sec.) proposed the list of awards, which were seconded by Sir JAMES KINGSTON FOWLER and carried, as follows:—

Children's Sanatorium, Holt, Norfolk (in consideration of the reservation of 10 children's beds during 1922 for the use of certain London hospitals)	£780
Daneswood Sanatorium, Jewish, Woburn Sands (in consideration of the reservation of two beds during 1922 for the use of certain London hospitals)	270
Devon and Cornwall Sanatorium, Didworthy, South Brent (£1080 of the grant in consideration of the reservation of eight beds during 1922 for the use of certain London hospitals)	1130
Eversfield Chest Hospital, St. Leonards	25
Fairlight Sanatorium, Hastings	25
Kelling Sanatorium, Holt, Norfolk (£540 of the grant in consideration of the reservation of four beds during 1922 for the use of certain London hospitals)	640
Mount Vernon Hospital, Northwood	100
National Association for the Establishment and Maintenance of Sanatoria for Workers, Benenden, Kent (£150 of the grant to mortgage debt and £1620 in consideration of the reservation of 12 beds during 1922 for the use of certain London hospitals)	1870
Northamptonshire Sanatorium, Creaton, Northants (£1080 of the grant in consideration of the reservation of eight beds during 1922 for the use of certain London hospitals)	1130
Royal National Hospital for Consumption, Ventnor	100

All Saints' Convalescent Home, St. Leonards	25
Beau Site Convalescent Home, Hastings	25
Brentwood Convalescent Home for London Children	25
Brooklands Home (Invalid Children's Aid Association), Worthing	25
Bushey and Bushey Heath Children's Convalescent Home	50
Chelsea Hospital for Women, St. Leonards (with a view to encouraging the admission of patients direct from the hospital)	100
Children's Convalescent Home, Beaconsfield	25
Children's Cottage Hospital, Cold Ash, Newbury*	25
Children's Home Hospital, Barnet*	25
City of London Hosp. for Diseases of Chest, Saunderton	50
Clevedon Sanatorium (Invalid Children's Aid Association), Broadstairs	25
Convalescent Home for Poor Children, St. Leonards	150
Convalescent Police Seaside Home, Hove	75
E. G. Anderson Hospital (Home of Recovery), Barnet	200
East London Hospital for Children, Bognor	50
Florence Emma Home (Invalid Children's Aid Association), Dover	25
Friendly Societies' Convalescent Homes, Dover and Herne Bay	50
Great Northern Central Hospital, Clacton	150
Great Northern Central Hospital, Southgate	250
Highgate Convalescent Home for Children, Highgate	50
Jewish Convalescent Home (Children), Brighton	75
King's College Hospital, Hemel Hempstead (the grant is made on condition that patients are admitted direct from the hospital)	120
London and Ascot Priory Convalescent Home, Bracknell	25
London and Brighton Female Convalescent Home, Brighton	25
London Hospital, Reigate	100

St. Andrew's Convalescent Hospital, Clewer	50
St. George's Hospital, Wimbledon	200
St. John's Home, Kemp Town (Brighton)	50
St. Luke's Home (Children), Woodley (Reading)*	25
St. Mary's Convalescent Home, Birchington	50
St. Mary's Home for Children, Broadstairs*	75
St. Michael's Convalescent Home, Westgate	25
St. Peter's Holiday House, St. Leonards	15
Samaritan Free Hospital, Amersham	75
Seaside Convalescent Hospital, Seaford	50
Sunday School Union Convalescent Home, Bournemouth	25
Sunshine Home, Hurstpierpoint	25
Surgical Home for Boys, Banstead*	15
Tilford Convalescent Home for Children, Farnham	15
Victoria Home for Invalid Children, Margate*	15
Victoria Hospital for Children, Broadstairs	200

Summary.

Grants to Consumption Sanatoria	6070
Grants to Convalescent Homes	3930
Total grants for the year 1921	£10,000

* In consideration of convalescent cases.

Correspondence.

"Audi alteram partem."

THE ÆTIOLOGY OF ADENOIDS.

To the Editor of THE LANCET.

SIR,—In his book on Adenoids Dr. Macleod Yearsley says that "adenoids are most prevalent in damp, cold countries," and to emphasise the fact puts this quotation in italics. Similarly, such an authority as Sir StClair Thomson says "there can be no doubt that adenoids are very much more frequent in temperate, cold, damp climates like our own." With the statistics and observations which have led laryngologists to this conclusion I need not deal. My observations simply correspond with them on this point. My special plea with regard to climate and adenoids was merely that we should not deliberately impose a cold and damp atmosphere on children, *by making them sleep in bedrooms with the windows* kept open in cold and damp weather. If we do, and then send them to the warm, germ-laden atmosphere of the schoolroom, we are only asking for trouble. To protect children from adverse climatic influences at night, and send them to something like open-air schools by day, would be acting more in accord with instinct, reason, and the dictates of evolution. Dr. Harry Campbell seems to admit that "damp predisposes to catarrh," but he says, "The climate of our country has been damp for thousands of years, but we have the evidence derived from disinterred skulls that it is only within comparatively recent years that adenoid disease has been common in this country." In this, again, I quite agree with him. Children were consistently protected from adverse climatic conditions, especially at night, until the end of last century and the beginning of this, and the great prevalence of adenoids appears to synchronise exactly with the deliberate abandonment of this precaution. Instead of the three cases recorded by Mr. W. Rushton being exceptional, they but illustrate what was going on all over the country. "The peculiar nature of the British diet" does not seem to account for the facts. Take, for example, the statistics of Gradenigo and Massei in Italy. Gradenigo, in his clinic at Turin (a subalpine climate), found on the *average one case in three*, while Massei, in Naples (a warm and genial climate), found only five cases in 15 years.—I am, Sir, yours faithfully,

Harley-street, W., Dec. 10th, 1921. J. SIM WALLACE.

To the Editor of THE LANCET.

SIR,—I note that Dr. Harry Campbell, whilst ascribing the frequency of adenoids to faulty gastric and intestinal digestion, the result of insufficiently masticated starchy food, admits that the food factor is not the only one in the causation of the disease. My contention is that if food plays any part at all in the ætiology of the disease it is a very slight one indeed and only of secondary nature. Dr. Campbell admits I am right in attributing to oft-repeated colds much of the active causation of adenoids, but when he seeks to attribute these colds to the status catarrhalis I think he is confusing cause with effect.

Against Dr. Campbell's dietetic theory I would like to advance the following:—

1. Adenoids are not peculiar to the British race. They are common in wet and damp localities—e.g., in the north of Italy. Meyer showed the Hebrew race to be especially affected. They occur in the Arctic circle amongst the Esquimaux and in the Malays on the Equator. They constitute no new disease. Meyer and Semon drew attention to the busts of antiquity and pictures of the Renaissance where the "adenoid facies" is frequently seen. And Hippocrates clearly referred to the condition.

2. Like Dr. Stewart Low, I have operated for the removal of adenoids on a large number of breast-fed children. In those cases attended by mouth-breathing it has only been necessary for the patient to wear a chin-strap at night for a fortnight and, if old enough, to carry out daily a graduated exercise for the catarrh to disappear, the tendency to catch cold to be markedly reduced, and for natural nasal breathing to replace the bad habit. It is true that gastric and intestinal catarrh is common in children the subjects of adenoids, but I am strongly of opinion that this is due in the main to direct extension from the naso-pharynx, and, to a lesser degree, to the swallowing of infected mucus. I have repeatedly come across cases of catarrhal jaundice in children with adenoids. And after removing the adenoid vegetations I have not known the jaundice to return.

3. The striking improvement in the general health which follows the curetting of the affected lymphatic surfaces in children with adenoids is also noticeable after local non-operative treatment to the nose and throat. With reference to unhealthy tonsils, I can fully endorse the experience of Mr. F. Stoker, as recounted in this month's issue of the *Practitioner*, with respect to infected tonsils. It is almost an everyday occurrence in my practice to note the great benefit a patient derives from the forcible evacuation of tonsillar crypts by pressure.

The cause of adenoids is repeated cold-catching *and the acquirement in youth of immunity from the* exanthemata. Why colds are of such frequent occurrence is a subject which largely concerns the skin and the subcutaneous vaso-motor reflexes, not digestion.—I am, Sir, yours faithfully,

HARRY MERRALL.

St. Anne's-on-the-Sea, Dec. 13th, 1921.

SOME HEART PROBLEMS.

To the Editor of THE LANCET.

SIR,—*In his address upon this subject*, appearing in your issue of Dec. 10th, Prof. E. H. Starling refers to the importance of the "limits set by the indistensible pericardium." I conclude from this that Prof. Starling considers one function of the pericardium to be that of a guardian of the heart, a protector against over-dilatation.

It does not seem to me that the pericardium possesses this power in the human subject. I have not the details of a few observations made in the post-mortem room at hand, but several years ago, *after tying all the vessels leaving or entering the* heart, outside the unopened pericardium, a glass tube was passed through the vena cava and another through a pulmonary vein, by means of which all the cavities of the heart were distended with water at a pressure of a column of about 3 *feet in height.* After thus filling all the cavities of the heart, it was ascertained how much water could still be held between the distended heart and the pericardium. With one exception there was sufficient room for the pericardium to hold water, although all four cavities of the heart were distended to their full extent. And it must be remembered that in life all four cavities of the heart could not be fully distended at the same time. The pericardium could only exert the power of restraining dilatation of the heart if it were to fit the ventricles closely in diastole, while the auricles were in systole. These observations were made on cases in which death had occurred from various diseases, such as typhoid fever, pneumonia, and also of some cases of cardiac disease.

The theory was once advanced that the remarkably rapid enlargement of the heart, which not uncommonly occurs in rheumatic pericarditis, could be explained by softening of the inflamed pericardium allowing dilatation of the heart. There are, however, two reasons why this theory cannot be accepted. In the first *place, in more severe non-rheumatic forms* of pericarditis—e.g., suppurative—there need be no dilatation of the heart. That is to say, the more severe forms of inflammation of the pericardium do not lead to softening of the pericardium, allowing dilatation of the heart. In the second place, the rapid enlargement

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

BIRKENHEAD.

ESTIMATED population for the year 1920, 153,951; birth-rate, 27·4; death-rate, 13·2; infant mortality rate, 102; death-rate from pulmonary tuberculosis, 0·76; and from other forms of tuberculosis, 0·37. Dr. D. Morley Mathieson gives a valuable table showing separately the death-rates from tuberculosis among males, females, and children under 5, for 10 years back. Such an analysis reveals the nature of the local problem, and should be given in every annual health report. As is usual in the case of seaports, where there is shipbuilding and much outdoor male occupation, the male death-rate is not much higher than the female. Dr. Mathieson tells us that the Birkenhead Corporation have agreed to use the county farm-colony at Wrenbury Hall, and that conferences have been held with neighbouring towns with a view to utilising more extensively the Leasowe Hospital for surgical tuberculosis. Out of 32 cases of ophthalmia neonatorum notified, one child lost an eye, and it has now been decided to supply practising midwives with a non-toxic preparation of silver nitrate. The provision of a municipal maternity hospital is under consideration. In his school report Dr. Mathieson states that a dental clinic has been established, and that a cleansing station, an open-air school, and X ray treatment for ringworm are needed. An interesting statement is given showing the results of inspection and treatment at the girls' secondary school. The percentage of defects found at the primary inspection in January, 74·5, was reduced to 14·5 at the third re-inspection in December.

RICHMOND (SURREY).

Estimated population for 1920, 35,572; birth-rate, 20·7; death-rate, 11·4; infant mortality rate, 57; tuberculosis death-rate, 0·9. Dr. C. W. Hutt (who has since become M.O.H. for Holborn) mentions that, in consequence of a letter from the President of the British Red Cross Society and the Order of St. John, arrangements have been made for the local voluntary aid detachment to take part in the maternity and child welfare scheme, adding that the experiment has been a marked success. The water-supply of Richmond is in part obtained from Petersham Well, which, since 1919, has been purified by chlorination. Pure chlorine gas is used, and is administered and measured by a Wallace-Tiernan plant. It is found with this water that a dose of chlorine as small as 1 part in 4,000,000 to 5,000,000 causes a degree of purification adequate for all practical purposes and superior to that obtained by open sand-filters. Dr. Hutt, in referring to a large camp which was held in the Old Deer Park last summer, recommends that in future the sanction of the Corporation for such camps be only given on condition that sanitary accommodation is provided.

WORCESTER.

Estimated population for 1920, 49,248; birth-rate, 23·2; death-rate, 13·01; tuberculosis death-rate, 1·06; infant mortality rate, 67. Dr. Mabyn Read says the efficiency of the public health service has been greatly increased by the appointment of Dr. Mary R. Mitchell to develop the maternity and child welfare work and to act as assistant tuberculosis officer, adding that Worcester stands sixth from best among the county boroughs for infant mortality rate. The fact that 37 of the 77 infant deaths occurred in the first month of life is evidence of the need for antenatal work. The local authority paid £31 13s. in fees to midwives for attendance on necessitous cases, and also spent £65 19s. on providing home-helps for 55 cases. £175 was spent on dental treatment for expectant and nursing mothers, £17 of which amount was received from the patients. Cases of ophthalmia neonatorum are treated at the ophthalmic hospital for one guinea per case, and collosol argentum has been supplied to midwives since October. The antenatal clinic is making good progress, and Dr. Read thinks the £185 spent on dinners for necessitous expectant and nursing mothers has been of great benefit in enabling the mothers to suckle their babies. Dr. Read expresses his gratitude to the voluntary workers who have helped to make the child welfare clinics successful, and mentions that new premises for the work are badly needed. The general housing conditions in the city, he states in conclusion, have not greatly improved during 1920. As only 16 new houses have been completed and there have been 500 more births than deaths, we should imagine they have become worse.

VITAL STATISTICS OF LONDON DURING NOVEMBER, 1921.

IN the accompanying table will be found summarised statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. The enumerated population (unrevised) of the last census has been used for calculating the rates in the table, with a deduction of the non-civilian population in the City of Westminster and in the borough of Woolwich. With regard to the notified cases of infectious disease it appears that the number of persons reported to be suffering from one or other of the ten diseases notified in the table was equal to an annual rate of 17·0 per 1000 of the population, enumerated at 4,476,238 persons; in the three preceding months the rates had been 8·6, 14·1, and 19·5. Among the metropolitan boroughs the lowest rates from these diseases were recorded in Kensington, Chelsea, the City of Westminster, St. Marylebone, the City of London, and Bethnal Green; and the highest in Hammersmith, St. Pancras, Islington, Bermondsey, Battersea, Greenwich, and Woolwich. The prevalence of enteric fever was about equal to that in the preceding month; of the 38 cases notified during the five weeks ended Dec. 3rd, 7 belonged to Kensington, 4 to Wandsworth, and 3 each to Paddington, Chelsea, St. Pancras, Southwark, and Greenwich. There were 20 cases of enteric fever under treatment in the Metropolitan Asylums Hospitals at the end of the month, against 32, 37, and 28 at the end of the three preceding months; the weekly admissions averaged 4, against 5, 7, and 4 in the three preceding months. The prevalence of scarlet fever showed a decline of 18 per cent. from the preceding month, but was higher than in any other month of the present or the preceding three years; this disease was proportionally most prevalent in Hammersmith, St. Pancras, Islington, Battersea, Deptford, Greenwich, and Woolwich. The Metropolitan Asylums Hospitals contained 5870 scarlet fever patients at the end of the month, against 3108, 4847, and 6154 at the end of the three preceding months; the weekly admissions averaged 802, against 407, 840, and 1000 in the three preceding months. Diphtheria showed a very slight fall in prevalence—about 1½ per cent.—from the preceding month, but was still higher than in any other month of the present year or the three preceding years; the greatest proportional prevalence of this disease occurred in Hampstead, Stepney, Bermondsey, Battersea, Greenwich, and Woolwich. The number of diphtheria patients under treatment in the metropolitan hospitals, which had been 1709, 2031, and 2777 at the end of the three preceding months, further rose to 3055 at the end of November; the weekly admissions averaged 416, against 209, 322, and 445 at the end of the three preceding months. Erysipelas was proportionally most prevalent in Finsbury, the City of London, Shoreditch, Bethnal Green, Poplar, Southwark, and Greenwich. The three cases of poliomyelitis belonged respectively to St. Pancras, Battersea, and Wandsworth; in the three preceding months the notified cases numbered 13, 10, and 5. Twelve cases of encephalitis lethargica were notified during November, against 5, 5, and 3 in the three preceding months; of these, 3 belonged to Southwark, 2 to Chelsea, and 2 to Lambeth. The notified cases of cerebro-spinal fever numbered 6, against 9, 5, and 3 in the three preceding months. The 34 cases of puerperal fever included 5 in Southwark, 4 in Stepney, and 3 in Paddington.

The mortality statistics in the table relate to the deaths of civilians actually belonging to the several boroughs, the deaths occurring in institutions having been distributed among the boroughs in which the deceased persons had previously resided. During the five weeks ended Dec. 3rd, the deaths of 6450 London residents were registered, equal to an annual rate of 15·0 per 1000; in the three preceding months the rates had been 10·8, 11·0, and 11·4 per 1000. The death-rates ranged from 11·9 in Lewisham, 12·4 in

THE CARELLI METHOD OF PERIRENAL INFLATION.

To the Editor of THE LANCET.

SIR,—With regard to Dr. Carelli's visit to London, referred to in your annotation of Dec. 17th on Gas Inflation of the Peritoneum in Radiography, I think it right to say that we owe his coming to Dr. F. G. Crookshank, physician to the French Hospital. Dr. Crookshank attended a demonstration by Dr. Carelli at Delherm's Clinic in Paris, and persuaded him to come to London. Dr. Carelli not only described his methods and skiagrams at the Royal Society of Medicine, but gave a demonstration of his procedure upon the living subject in the X ray department at the French Hospital with his own inflation outfit. This is a simple apparatus, easy to duplicate. Apart from this, only the ordinary resources of the department were employed, and two excellent radiographs were obtained. Oxygen was used, not CO_2, as the latter was not available. This proved rather an advantage under the circumstances, as I was able to repeat the exposures more than an hour later in my own rooms. All the plates—which were exhibited at the Royal Society of Medicine—showed the adrenal body, and in some the vessels could also be seen.

That the patient suffered but little discomfort, and was able to move freely a few minutes after the inflation, can be testified to by several medical men who were present.

I am, Sir, yours faithfully,
F. HERNAMAN-JOHNSON, M.D.,
Director, X Ray and Elect. Service,
London, W., Dec. 17th, 1921. the French Hospital.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

An Irish Session.

PARLIAMENT reassembled on Wednesday, Dec. 14th, for a special session to consider the articles of agreement entered into between the British Cabinet and the Irish delegation of plenipotentiaries with regard to the future government of Southern Ireland as an Irish Free State. The session was opened by His Majesty in State, and the gracious speech from the Throne was exclusively confined to the Irish agreement. After debates in both Houses, which lasted three days, the agreement was ratified in the House of Lords by 166 votes to 47 and in the House of Commons by 401 votes to 58.

The session was prorogued on Monday, Dec. 19th, to Tuesday, Jan. 31st.

HOUSE OF COMMONS.

FRIDAY, DEC. 16TH.

Importation of Menthol.

Mr. NEWBOULD asked the President of the Board of Trade if he was satisfied that the procedure of his department in placing substances, such as menthol, amongst the commodities which were liable as fine chemicals to a duty of 33⅓ per cent., and afterwards attaching the letter R to the names of these substances, thereby exempting them from duty, was not calculated to create considerable confusion; and was he prepared to give an undertaking that no such action would be repeated without public inquiry, of which notices had been previously circulated in the public press, instead of in a weekly journal published by the Board of Trade, of whose existence few traders were aware.—Mr. STANLEY BALDWIN replied: Certain amendments have been made to the lists as originally issued under the Safeguarding of Industries Act, but all the amendments so far made restrict the scope of the original lists. It is obvious that in lists such as those in question it must be necessary to make some corrections, and I see no reason to modify the procedure adopted. I should add that I do not accept the statement at the end of the question as being correct.

Dr. MURRAY asked the President of the Board of Trade where his department obtained the menthol which they stated was purer than the ordinary imported menthol and which was the basis of the addition of the letter R in the Board of Trade list which defined the Key Industries Schedule; whether this menthol so obtained was a commercial article before objection was lodged to the inclusion of menthol in the list; and whether, in fact, it was a commercial article at all.—Mr. STANLEY BALDWIN replied: A re-crystallised menthol of substantially better quality than the Japanese menthol ordinarily imported has been prepared in Germany by a well-known firm and was listed as "Menthol pure in crystals" in their English catalogue as long ago as 1911. I am informed that during recent years at least one English firm has been re-crystallising menthol and selling small quantities.

Importation of Santonin, &c.

Dr. MURRAY asked the President of the Board of Trade whether, in view of the decision given by the Lord Chancellor's referee on Dec. 10th in respect of santonin and of the grounds given for that decision which affected by implication a large number of commodities contained in the list published by the Board of Trade under the Key Industries Schedule of the Safeguarding of Industries Act, he would be prepared to extend beyond Jan. 7th, 1922, the date up to which objections to the list might be lodged, at any rate until he had officially announced the scope of the action which he intended to take as a result of the decision given, especially as regards all those natural substances which were so closely related to santonin as to be governed by exactly the same principles—e.g., salicin, menthol, mannite, lactose, eserine, &c.—Mr. STANLEY BALDWIN replied: No, Sir. I am not prepared at present to undertake to extend the period during which complaints may be lodged which the Board must refer to the referee; but should the principles on which the decision mentioned was based be maintained the list will of course be revised accordingly, and I shall be prepared to consider at any time any representations which may be made to me in that regard.

Indian Opium Statistics.

Mr. GILBERT asked the Secretary for India what was the acreage in India now under cultivation with the opium poppy; how many chests of Indian opium were now exported annually; what were the destinations of this exported opium; and whether any and, if any, how much was converted into prepared opium for smoking.—Colonel GIBBS (Treasurer of the Household) replied: The total area under poppy cultivation in British India amounted to 156,435 acres in the year 1919–20. 9823 chests of opium were exported in that year. The countries which imported this opium were the Straits Settlements, Dutch East Indies, Siam, French Indo-China, Japan, United Kingdom, Hong-Kong, British North Borneo, Ceylon, Mauritius, and the Fiji Islands. I am not in a position to state how much of the raw opium exported from India to other countries is there converted into prepared opium for smoking.—Mr. BARNES: Can the hon. and gallant gentleman say if the Government are working in full harmony with the organisation under the League of Nations for the reduction or suppression of this trade?—Colonel GIBBS: I am not in a position to state that myself, but I will tell my right hon. friend what the right hon. gentleman says.—Mr. BARNES: Will the hon. and gallant gentleman make inquiries on the matter?—Colonel GIBBS: Yes, Sir.

Medical Stores for Russia.

Mr. ANEURIN WILLIAMS asked the Prime Minister whether His Majesty's Government was aware that the number of starving people in the Russian famine area was far beyond the reach of private charity; and whether the Government had decided to recommend the granting of credits to the Russian Government for the purpose of food without which millions of people must starve during this winter.—Mr. CHAMBERLAIN (Lord Privy Seal) replied: The Government are fully alive to the serious nature of the famine in Russia. The answer to the second part of the question is in the negative; the hon. Member is no doubt aware that Parliament has voted a sum of £100,000, representing the present value of Government stores, chiefly medical, to be placed at the disposal of the Red Cross Society for the relief of famine in Russia. The original value of these stores was £250,000; their present day value is £100,000.—Replying to further questions by Mr. WILLIAMS, Viscount CURZON, and Sir C. YATE, Mr. CHAMBERLAIN said: The sum which has been voted by the House was voted to send stores, mainly medical stores, which were to be at the disposal of the Red Cross for use in Russia. I am not aware of any proposal as suggested that with other powers we should collectively vote money from national funds, but it is quite obvious that in dealing with any matters of this kind we must have regard at the present moment to the condition of our own people.

Treatment Allowances.

Mr. JOHN DAVISON asked the Minister of Pensions whether he would inform the House how many men had been struck off treatment allowances in consequence of the circular of the Ministry dealing with the supervision of out-patient treatment; how many of those struck off allowances were certified by the Ministry of Pensions fit for any work; how many were ordered to continue treatment without allowances;

TERRITORIAL ARMY RESERVE.

Maj. A. Greenwood, from Genl. List, R.A.M.C., to be Lt.-Col.

ROYAL AIR FORCE.

Group Capt. David Munro to be Air Commodore.

INDIA AND THE INDIAN MEDICAL SERVICE.

Surg.-Commodore C. W. A. Newport, R.N., is accompanying the Prince of Wales on his tour through India, and Lieut.-Col. F. O'Kinealy, Bengal, has been appointed Chief Medical Officer to His Royal Highness. Maj.-Gen. W. H. B. Robinson, C.S.I. has been appointed President of the Governing Body of the Bengal State Medical Faculty, vice Lieut.-Col. F. O'Kinealy, C.I.E., resigned; and Lieut.-Col. D. C. Kemp Civil Surgeon, Cochin, on return from leave. Maj. K. Cantlie has been granted one year's leave. On transfer from Lahore Lieut.-Col. J. G. G. Swan, C.I.E., has resumed charge as Civil Surgeon, Ferozepore. Maj. D. H. Rai, M.C., has assumed charge of the Civil Surgeon, Ludhiana. Maj. R. B. Seymour Sewell, surgeon naturalist, Marine Survey, has been granted one and a half years' combined leave. On return from military duty Lieut.-Col. A. M. Fleming has been posted to Asugor as Civil Surgeon to the executive and medical charge of the Saugor District Jail. Capt. A. F. W. da Costa, officiating civil surgeon, has reverted to his substantive appointment of Assistant Surgeon and been posted to the main hospital, Asugor. Maj. W. W. Jeudwine has handed over charge of the duties of Superintendent of the District Jail at Rawalpindi to Lieut.-Col. P. St. C. Moore. Maj. C. A. Godson has taken over charge as Police Surgeon, Calcutta, during the deputation of Lieut.-Col. N. P. Sinha to Simla; and Maj. M. S. Irari has been posted to Bombay.

Obituary.

JOHN HARLEY, M.D., F.R.C.P.Lond.,

CONSULTING PHYSICIAN TO ST. THOMAS'S HOSPITAL AND TO THE LONDON FEVER HOSPITAL.

We regret to announce the death of Dr. John Harley, which occurred at Pulborough, Sussex, on Dec. 9th. As a physician and as a teaching member of the staffs of two great general hospitals in London, he was a familiar feature in medical circles for 30 years.

John Harley was born in 1833, being at the time of his death in his eighty-ninth year. He received his medical education at King's College Hospital, where he entered as a senior scholar and where he later became a fellow. He graduated in medicine at the University of London in 1860, and took the M.R.C.P. Lond. in the same year. After holding the junior appointments at the hospital he was appointed assistant physician, a post which he held for eight years, and where his popularity among his pupils was marked upon his leaving them by a spontaneous presentation. In 1872 he was appointed assistant physician at St. Thomas's Hospital, having in the meantime been elected F.R.C.P. His connexion with the Royal College of Physicians of London was always a close one. He was Goulstonian lecturer in 1869 and an examiner at the College for three separate periods between 1875 and 1886, and in 1889 he delivered the Lumleian lectures. He took as his subject enteric fever, and these lectures, which were published in abstract in The Lancet, created considerable sensation. They were fluent and attractive, but they were also directed against modes of thought which were commonly accepted concerning a common disease. Harley had the courage to utter heretical views, and not for the first time, as he had already adopted a singular attitude concerning the relationship between scarlet and enteric fevers, believing both to have a common origin in catarrh. The intention of the Lumleian lectures on enteric fever was to lay stress on the influence of exposure to cold, and to subvert the doctrine of contagiousness, if not that of the specificity of typhoid fever, itself. Undoubtedly his line of thought was cleverly maintained, and undoubtedly also it is a good thing that orthodox beliefs should now and again be challenged and their too servile acceptance be prevented, but Harley made no converts, for his pathological foundations were seen to be unsound. He was elected on the Council of the Royal College of Physicians in 1890, and in 1893 was appointed consultant physician to St. Thomas's Hospital.

Dr. John Harley never attained to the professional position which his wide attainments, energy, and sympathetic nature seemed to fit him for, and the reason for this is indicated in what we have already said and is substantiated by the following note which we have received from one of his distinguished colleagues.

S. J. S. writes:—

John Harley came to St. Thomas's Hospital with a distinguished record from King's College, and later his appointments and writings added to that record. He was a man of ability who displayed a keen interest in medicine and in many other subjects. He had a suave and attractive manner, formed independent opinions, and expressed them with confidence. How, then, it may be asked, was it that he failed to earn greater distinction in his profession? The probable answer is that he so exaggerated and distorted the good points in his character that so far from forwarding his interests they became obstacles to success. Take, for instance, his genial manner. He would meet everyone with a smile, a half bow, and a prolonged and vigorous hand-shake; but the whole thing was so overdone that it became a standing joke. One student would make a bet with another that he would shake hands with Harley so many times before he got from the central hall to his ward, and by running up staircases and appearing suddenly round corners he would probably win his bet. Indeed, this universal hand-shake sometimes gave rise to ludicrous scenes. On one occasion one of the resident staff hurried up to Dr. Harley's ward to see a case he had just admitted, and arriving in the ward about five minutes before Harley was due he was surprised to see the "Sister" standing pensively in front of the fire-place, facing the door, with an inkstand in one hand and blotting paper in the other. On being asked what this meant, she replied that it was to avoid the handshake.

The opinions which Harley formed on different events and different scientific subjects were often quite out of keeping with modern knowledge, and ignored modern methods of investigation; but once having stated them nothing could move him to reconsider them. He apparently never dreamt of the possibility of his being wrong. The result was that no one took Harley seriously, and he lost the influence and respect he might otherwise have gained. There is no doubt that he was a man of ability, but he failed to turn it to good account.

From the same source, and from others of Harley's colleagues, we have received tributes to his goodness and generosity, showing that his genial manner was no assumption but covered great kindness of heart. He would constantly assist his poorer hospital patients from his purse, and befriend his old students in times of need. He was a man of considerable all-round accomplishment rather than a great physician.

GREGORY PAUL JORDAN, M.B., C.M.Edin., LL.D. Hong-Kong.

Dr. G. P. Jordan, who died in London on Dec. 4th at the age of 64 years, was port health officer at Hong-Kong and professor of tropical medicine in the University, where he was for a time acting Vice-Chancellor. Graduating in medicine at the University of Edinburgh in 1880, he studied at St. Thomas's Hospital, London, Cambridge, Vienna, and Paris, taking the M.R.C.S. Eng. in 1884. He went out to Hong-Kong as colonial surgeon, on the abolition of that post became port health officer, and with Manson and Cantlie helped to found what is now known as the old Medical College. He was on the staff of the Alice Memorial Hospital and during the war took on the surgical superintendence of police. Devotion to work was already impairing his health when he accepted the onerous position of acting Vice-Chancellor of the University on Sir Charles Eliot's departure for Japan, but he had the satisfaction of knowing that his brief stewardship left the institution in a sounder financial position. His services were recognised by the bestowal of an honorary LL.D. degree. A Freemason, a noted amateur photographer, and a keen sportsman, Jordan was a popular figure in Hong-Kong, where his presence will be missed by all classes.

Fair, Laurence Phillips, Michael G. J. Powell, Richard Scale, Allen E. Drotske, Donald H. Saayman, Harry C. Dundon, Robert E. Fausset, Gilbert Kirker, Max Sayers, Rupert L. Hill, Henry L. Hanna, George S. Moran, James V. Williams, Robert R. Baker, and James R. Wills.

Surgery.—Gilbert M. Irvine and Theunis de Bruijn (passed *on high marks*), *Cornelis Derksen Dijkman, Daniel Hugo,* Izak G. Sacks, Doris Holland, Leopold Stazunsky, Thomas G. Warham, William A. Murphy, Richard Scale, Charles Theodore de Mornet Villet, Ivan Marais, Leon O. Vercueil, Abraham Agranat, Max Elion, Donald H. Saayman, Cecil de Lisle Shortt, John D. Thompson, Alfred H. N. Todd, Charles E. Ovendale, William B. Briggs, Jacob Hofman, Herbert Hall, George C. B. Robinson, *Beryl Frances E.* Cockle, Rita Dillon-Leetch, Max W. Kaplan, and Richard Lang.

DIPLOMA IN PUBLIC HEALTH.

Part I.—Richard W. Power, Edward G. Campbell, and William L. Young.

Part II.—Frederick W. Godbey, William B. J. Pemberton, Alan G. Wright, Jessie O. Gilbert, and Charles L. McDonogh.

UNIVERSITY OF EDINBURGH.—At the graduation ceremonial held on Dec. 16th the following degrees were conferred :—

DOCTOR OF MEDICINE.

Garth Ap Thomas, John J. Rouse Binnie, Alice Bloomfield, *Cecil C. Brown, Samuel B. B. Campbell, †Vincent T. Carruthers (in absentia), *Alexander G. Coullie (in absentia), *Francis A. E. Crew, *Herbert R. B. Gibson (in absentia), *Robert L. Girdwood (in absentia), George H. Gunn, Gustav Lange (in absentia), David Lennox, John S. Lloyd, *Benzion Morrison, Hubert Patley, Ella F. Pringle, Richard H. Pulipaka, Andrew O. Ross, Joseph H. M. Sandison, Herbert J. Slane (in absentia), and Arthur K. Towers.

* Commended for thesis. † Highly commended for thesis.

BACHELOR OF MEDICINE AND BACHELOR OF SURGERY.

Reuben Abramsky, John C. Adam, Cecil S. Appleyard, Elias Arosemena, Charles G. Auld, Charles T. B. Benson, Lionel R. Bergson, Susan A. Binnie, John M. Blair, Roger P. Bliss, John M. Bonar, G. Brewster, Agnes G. Brough, Douglas L. Brown, Charles Brownlee, William S. Burr, Karl F. Caird (second-class honours), Arthur Campbell, Donald Campbell, George G. Campbell, Charles G. Catto, Clarence Henri-François de Chalus, Edwin Clark, Donald R. Clarke, Matilda L. Craig, Douglas R. Cramb (second-class honours), John C. Cruickshank, Alexander H. Deighton, John A. Douglas, Alexander MacGregor Duff, Jeannie P. Dunn, Katrine Dunn, Evelyn B. G. Ewen, Gordon B. Flint, Charlotte E. Forsyth, John A. Fraser, Eileen R. Freeman, Frederic L. A. Gacé, Marjorie Geen, Owen S. Gibbs (second-class honours), Norris Giblin, Doris M. Gibson, Helen E. Gibson, Andrew R. Gilchrist, Ion S. Hall, Thomas Harrison, Isabella M. Hay, William B. E. Hughes, Elspeth J. Hunter, Richard H. R. Innes, Barnett Isaacson, Inez M. Y. M. Jenkins, Charles I. I. Jones, Joseph O. Kelly (first-class honours), Marjorie C. Kerr, Arthur King, Johan Lovius, Patrick J. McDiarmid, Jane W. Macdonald, William S. Macdonald, George S. Mackay, George W. J. Mackay, John C. MacKay, Henry D. McKinna, Herbert McNair, John W. Mason, Donald S. Middleton (second-class honours), Ian C. Middleton, Ann L. Morrison, Quazi Mahammed Musa, Stanley S. Nicholson, George Ogilvie, Montague M. Ostrowick, James W. T. Patterson, Harry R. Potter, Alexander M. W. Rae (second-class honours), Louis Ratnayaké, William B. Reid (second-class honours), Charles A. Robson, Abraham Sanders, Ernest L. Sanders, Gerald G. Sanders, Margaret M. Sands, Manmatha Nath Sanyal (in absentia), Gordon S. Scott (second-class honours), Charles M. Seward, John McDonald S. Slater, Allen T. Sloan, Thomas R. C. Spence, George D. Steven (second-class honours), Francis M. Stewart, Alexander Stuart, Alister Sutherland, Arumana Krishnan Tampi, Marion C. Taylor, Lewis Teitelman, David W. C. Tough, George A. Velluot, Kakumanu Vullakki, George B. Walker, John Walker, Peter K. Walker, Sarah B. H. Walker, Kenneth B. Williamson (second-class honours), Arthur J. Wilson (second-class honours), John T. Wilson, and John H. Wright.

DIPLOMA IN PUBLIC HEALTH.

William P. S. Johnson.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.—At a meeting of the College held on Dec. 16th the following candidates, having passed the requisite examinations, were admitted Fellows :—

Ennis R. Chambers, Cecil B. Clarke, Jacob H. Dove, Ernald D. Smith, Vinayak Balvant Gokhale, John W. Hall, Norman Hodgson, Ernest W. Ingle, Merwan Sorab Irani, Venkatras Manjunath Kaikini, Robert Mailer, Robert B. P. Monson, Kali Sahai Nigam, Arthur L. Sheppard, Phineas A. Smuts, David Steven, Robert L. Stewart, and Thomas J. R. Warren.

Dr. George Mackay and Mr. Charles W. Cathcart, C.B.E., were re-elected representatives on the Board of Management of the Royal Infirmary, Edinburgh for the ensuing year.

ROYAL INSTITUTION.—The first of the Christmas Course of Juvenile Lectures at the Royal Institution on Electric Waves and Wireless Telephony, by Prof. J. A. Fleming, will be delivered next Thursday (Dec. 29th) at 3 P.M. on Surface Waves on Liquids. The succeeding lectures will deal with Waves in Air, the Telephone, Electric Oscillations, Electric Waves, and Wireless Telephony.

UNIVERSITY OF LONDON.—A meeting of the Senate was held on Dec. 13th, Sir Sydney Russell-Wells, the Vice-Chancellor, being in the chair. Mr. R. H. Aders Plimmer, D.Sc. Lond., was appointed as from Jan. 1st, 1922, to the University Chair of Chemistry tenable at St. Thomas's Hospital Medical School. Dr. Plimmer was educated at University College, London, and at the Universities of Geneva and Berlin. From 1902 to 1904 he was Grocers' Company's Research student at the Lister Institute of Preventive Medicine, and in the latter year was appointed assistant for physiological chemistry at University College, where he was later elected to a Fellowship and appointed to teach chemistry to medical students. In 1912 the Senate conferred on him a readership in physiological chemistry. Since 1919 he has been head of the biochemical department of the Rowett Research Institute of Animal Nutrition and North of Scotland College of Agriculture, and research lecturer in applied biochemistry in the University of Aberdeen. He is co-editor with Prof. F. G. Hopkins of "Monographs on Biochemistry," and is the author of numerous publications on chemical and physiological subjects.

The Royal Dental Hospital and London School of Dental Surgery was continued as a School of the University in the Faculty of Medicine (in dentistry only) for a further period of three years. Regulations for the new degree of Bachelor of Dental Surgery were approved for internal students.

Sir Sydney Russell-Wells was reappointed the representative of the University on the General Medical Council for 1922–23, and Prof. A. D. Waller, F.R.S., was appointed to represent the University at the unveiling of a memorial to Pasteur, in commemoration of the 100th anniversary of his birth, to take place at Strasbourg.

HONOUR TO A MEDICAL MAN.—The medal of the "Reconnaissance Française" has been bestowed upon Dr. Alfred S. Gubb, of Algiers, by the President of the French Republic in recognition of his devoted services in the work of the French Red Cross.

LECTURES ON HOSPITAL ADMINISTRATION.—A three months' course of lectures and demonstrations on hospital administration will be given at the North-Western Hospital, Lawn-road, Hampstead, London, N.W., by Dr. E. W. Goodall, on Mondays and Thursdays at 5.15 P.M., beginning on Monday, Jan. 9th, 1922. Medical men desiring to attend the course of instruction are required before attending at the hospital to pay the fee of £3 3*s.* to the Clerk to the Metropolitan Asylums Board, Embankment, London, E.C. 4, giving their full name and address.

POPLAR HOSPITAL FOR ACCIDENTS.—The annual festival of this hospital was held at the Holborn Restaurant on Dec. 13th. Sir Joseph Broodbank said that whereas before the war the annual cost of the hospital was about £11,000, to-day it was £20,000. During the last seven or eight years they had saved three-quarters of the £50,000 required for new buildings. Working men themselves gave £1700 per annum direct to the funds, in addition to the 2*s.* 6*d.* per day which now had to be charged to in-patients. Every year 50,000 people passed through the hospital, and so frequent were accidents in dockland that 160 cases were treated daily. Viscount Knutsford congratulated the management upon possessing the only hospital in London that was in a prosperous condition.

LONDON PANEL COMMITTEE DINNER—The second annual dinner organised by the Local Medical and Panel Committee of London and held at the Holborn Restaurant on Dec. 15th, was followed by a dance and was altogether a pleasant social affair. Two of the invited guests occupied important positions at the Ministry of Health—viz., Mr. R. W. Harris, and Dr. J. Smith Whitaker, while the third, Sir Thomas Neill, was the newly-elected chairman of the London Insurance Committee. Dr. H. J. Cardale, who presided, and Dr. Lauriston Shaw, who replied to the toast of "The Committee," also spoke, the message of all five speakers being summed up in the sentence: "The eyes of the world are turned on London as an object-lesson in the success *or failure of the insurance principle in medical* practice." Sir Thomas Neill, who spoke with warmth, said that the worse the neighbourhood and the more fragile the community, the higher the class of medical man required there. Dr. Smith Whitaker gave an instructive historical survey of the development of contract practice. He was himself instrumental in 1895 in organising a local medical society in Great Yarmouth, which insisted on three essential points in club practice: free choice on the part of doctor and patient, representation of the medical profession in the management, and a medical committee elected by the practitioners doing the work, to be consulted on conditions of employment. These three principles were, he said, first accepted by the British Medical Association and were then incorporated in the Insurance Act of 1911.

of the heart occurring in rheumatic pericarditis is not simply dilatation, it is a form of hypertrophy. In some way, possibly by interference with the metabolism, the heart may double or even treble its weight in about a week, showing that the enlargement is due to some peculiar effect of the rheumatic toxin, and is not a mere mechanical result of inflammation of the pericardium.

The above-mentioned sample experiments would lead me to believe that the normal pericardium is far too capacious to exert any restraining influence on the heart; and some cases of death from rheumatic pericarditis, seen in the post-mortem room, would indicate that there may be room within the cavity of the pericardium for the heart quickly to increase to three times its usual size.

I am, Sir, yours faithfully,
Norwich, Dec. 17th, 1921. THEODORE FISHER.

THE ORGANISATION OF MEDICAL EDUCATION.

To the Editor of THE LANCET.

SIR,—May I be allowed to support the general principle enunciated by Sir Clifford Allbutt and "C. L." in your columns last week? I found my claims to do so on the fact that I am an ophthalmic surgeon who has had experience of general practice; and further, that I am interested in psychology.

The inefficiency of the present curriculum is vividly exemplified by the inability of many general practitioners to cope with serious ophthalmic conditions, such as ophthalmia neonatorum. It is a deplorable fact that many babies are allowed to become blind through ophthalmia neonatorum in spite of the fact that the mother and child have been under the care of a doctor. The Council of British Ophthalmologists has urged the General Medical Council to insist upon examination in ophthalmology of candidates for the qualifying diplomas. Owing to the overcrowded curriculum students will not, indeed cannot, devote sufficient attention to a subject which they can neglect with impunity so far as the qualifying examination is concerned. The Council of British Ophthalmologists has been rebuffed by the General Medical Council, but it is encouraging for them to learn from your columns (THE LANCET, Dec. 10th, p. 1238) that the Examination Committee of the General Medical Council has passed a resolution supporting in every respect the recommendations of the ophthalmologists.

Yet the carrying out of these recommendations will add another straw to the camel's burden—and it is by no means the only straw. Oto-rhino-laryngology and psychology also demand consideration. With regard to the latter subject, I should like to support "C. L.'s" remarks. The student devotes many years to the study of the human body, yet receives little or no instruction in the working of the human mind. A large proportion of the general practitioner's work is the treatment of nervous disorders which manifest themselves as mental abnormalities. He has to cope with them empirically, unaided by any knowledge of the underlying scientific principles. It cannot be doubted that the course of instruction in physiology should be followed by one on the principles of psychology, and that psycho-pathology should form an integral part of the course in medicine.

Everyone will agree that the present curriculum is overcrowded. The impossible is attempted—viz., that of turning out general practitioners and hospital physicians and surgeons from the same mill. Seeing that the majority of students will become general practitioners, and that all medical men should be equipped with the knowledge which is most necessary for general practitioners, it would appear obvious that the qualifying curriculum and examinations should be designed specially for the requirements of this preponderant class. In other words, it should have a definitely utilitarian aim. Much of the smatterings of scientific knowledge now regarded as essential should be eliminated, leaving room for matters of greater practical importance.

It will be objected that this view is subversive of scientific education. In my opinion, however, the non-utility, "pure" science theory of education has been exaggerated to the detriment of scientific education, and can be shown to be unsound on biological and psychological grounds. I contend that it is not only possible to teach the scientific method while devoting special attention to utilitarian aims, but that for the majority of people it is the only way.

It is becoming increasingly evident that the medical curriculum must be revised, and it is a fortunate occurrence that so distinguished a leader of British medicine as Sir Clifford Allbutt has given such an admirable lead to the movement.

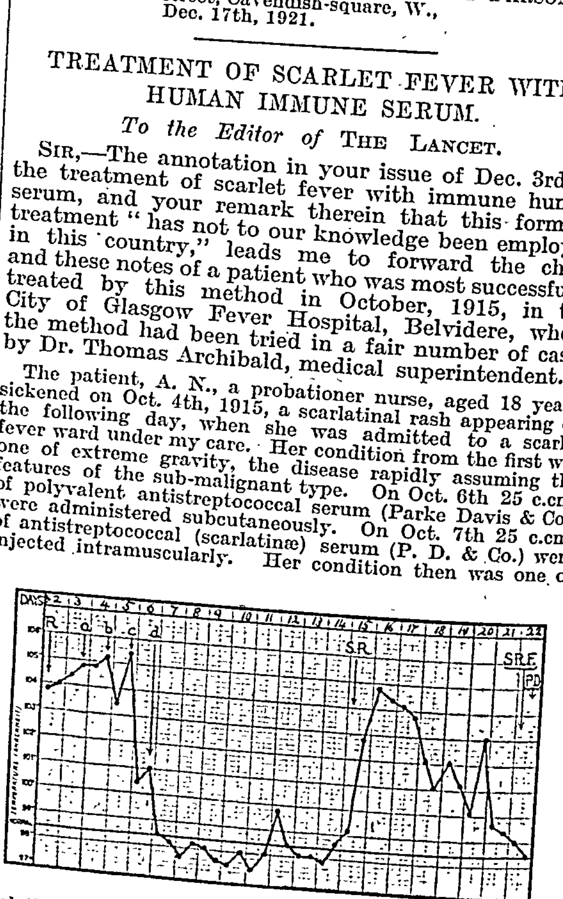
I am, Sir, yours faithfully,
J. HERBERT PARSONS.
Queen Anne-street, Cavendish-square, W.,
Dec. 17th, 1921.

TREATMENT OF SCARLET FEVER WITH HUMAN IMMUNE SERUM.

To the Editor of THE LANCET.

SIR,—The annotation in your issue of Dec. 3rd on the treatment of scarlet fever with immune human serum, and your remark therein that this form of treatment "has not to our knowledge been employed in this country," leads me to forward the chart and these notes of a patient who was most successfully treated by this method in October, 1915, in the City of Glasgow Fever Hospital, Belvidere, where the method had been tried in a fair number of cases by Dr. Thomas Archibald, medical superintendent.

The patient, A. N., a probationer nurse, aged 18 years, sickened on Oct. 4th, 1915, a scarlatinal rash appearing on the following day, when she was admitted to a scarlet fever ward under my care. Her condition from the first was one of extreme gravity, the disease rapidly assuming the features of the sub-malignant type. On Oct. 6th 25 c.cm. of polyvalent antistreptococcal serum (Parke Davis & Co.) were administered subcutaneously. On Oct. 7th 25 c.cm. of antistreptococcal (scarlatinæ) serum (P. D. & Co.) were injected intramuscularly. Her condition then was one of intermittent rambling delirium, the rash being generalised and livid. On that night (7th) Dr. Archibald suggested the employment of a human serum. Blood was obtained from Nurse A., a patient in the ward, who was in her fifth week of convalescence from a sharp uncomplicated attack of scarlatina. On the afternoon of the 8th 34 c.cm. of the separated serum were injected intramuscularly. On the same day blood was obtained from Nurse S., a patient in an adjoining ward, who was in her fourth week of convalescence from simple scarlatina. 33 c.cm. of the separated serum were given intramuscularly on the afternoon of the 9th. The results are evident on the chart.



Scarlatinal rash appeared at R. Antistreptococcal serum was given at *a* and *b*. Convalescent human serum at *c* and *d*. Serum rash appeared at S.R. and faded at S.R.F. At P.D. profuse desquamation set in.

This case brings out the point which you mention—termination by crisis. Beyond serum rash and sickness, which appeared on the 18th, convalescence was uninterrupted.

I am, Sir, yours faithfully,
Glasgow, Dec. 9th, 1921. C. CAMERON.

Notes, Short Comments, and Answers to Correspondents.

THE HEALTH OF INDIA AFTER THE WAR.[1]

DURING the year 1919, although active hostilities with Germany had ceased towards the end of the previous year, various circumstances combined to affect adversely the health statistics of British troops and of the Indian Empire generally. The mass of figures to be dealt with explains the delay in the issue of the Report.

The garrison units, and to some extent the Territorial force, were largely composed during 1919 of elderly men and soldiers who had been found temporarily unfit for active service in Mesopotamia and East Africa; and these were naturally least able to accommodate themselves to the climatic conditions of India. Moreover, the troops arriving from home contained a large proportion of young men under 20 years of age, and in many instances not well suited for tropical service. There was also a general unrest in Northern India, and actual hostilities had to be undertaken along the Afghanistan and North-West Frontiers; large numbers of men had therefore to be retained in the plains during a very trying hot weather, who would, under normal conditions, have been serving in the hills.

The average strength of European troops was 56,561, as compared with 87,982 in 1918, and 69,440 in the pre-war quinquennium, 1910–14. The admissions to hospital were in a ratio of 972·1 per 1000, the deaths 7·74, the invalids sent home 76·40, and the average constantly sick 57·39. These ratios are to be compared with the corresponding ones of 1918, which were 1030·2, 16·19, 22·81, and 60·0 respectively; and with those of the pre-war quinquennium (1910–14), which were 567·2, 4·51, 7·03, and 30·13 per 1000. There was a slight reduction in the admissions and number constantly sick and a great improvement in the mortality compared with the previous year; but the invaliding was more than trebled, and on the whole the conditions were still far removed from the normal for European troops in India. Of the 15 large stations (having over 1000 average strength, and excluding Colaba, where the circumstances are exceptional), Rawal Pindi (with 1360·8 admissions and 85·0 constantly sick per 1000), Delhi, Ferozepore, Lucknow, and Bangalore (790·5 and 53·8), had more sickness than in 1918; but only at Secunderabad and Lucknow were the death-rates (7·03 and 10·12) higher than in the previous year (6·76 and 7·94).

Disease among the Troops.

Influenza, which had been so prevalent and fatal in 1918, died out during the first quarter of 1919, and was generally of a mild type; the admission and death ratios were 25·2 and 0·25, compared with 219·5 and 8·81 in the previous year; at Colaba there were 493 admissions, chiefly in May and June, and 2 deaths (263·2 and 1·07 per 1000); the disease was prevalent in Bombay at the time.

For *malaria* there were 217·8 admissions and 0·74 deaths per 1000, accounting for 22·4 per cent. of the total admissions to hospital and 9·6 per cent. of the total mortality. The admission ratio was less than in 1917 and 1918 (227·9 and 269·2), but much in excess of the quinquennial average (117·2) for 1910–14. The mortality (0·74 per 1000) was also high; in the quinquennium, 1910–14, it had averaged 0·13 per 1000; in the successive years, 1915–18, this ratio had been 0·36, 0·31, 0·48, and 0·65; whether this be due to a real increase in severity of the disease or to increased strictness in diagnosis is doubtful. The list of important stations, having a strength of over 1000 troops, where malaria was prevalent is headed by the new capital of India; at Delhi the actual admissions numbered 615, being in a ratio of 511·6 per 1000; then follow Colaba and Bombay combined (374·3), Rawal Pindi (342·7), Peshawar (333·6), and Lahore (323·4). At Delhi it is stated that "almost every case originated in the Fort. New cantonments and the Kingsway Camp were free from infection. There are no breeding places in the Fort itself, but it harbours innumerable anopheline mosquitos. . . . The chief breeding grounds are in the Civil *Gung* adjacent to the Fort. The civil authorities are gradually (*sic*) proceeding with an extensive anti-mosquito scheme in that area. . . . Prophylactic quinine was issued daily under close supervision and proved [to be] of no avail and rendered laboratory diagnosis more difficult." The qualifying adverb "gradually," as applied to a measure of disease prevention that has been accepted as of paramount necessity for 20 years, appears to be somewhat unsuitable. At Colaba and at Peshawar it is stated that a third of the admissions were relapses; at the latter station "the system of drainage and irrigation in vogue has always been responsible for the high incidence of malaria. The bulk of the water is carried in open earth channels, which are badly graded." At Poona the Bhairoba nullah is the anopheline breeding centre in the station, and until leakage into the nullah from the canal is prevented no marked success can be expected. At 45 hospitals 9604 cases were analysed; of 4151 fresh cases, 66·47 per cent. were of the benign tertian type, 15·68 per cent. malignant tertian, and 0·39 per cent. quartan, the remainder (17·46) being "clinical" cases. Of 5453 relapses the corresponding percentages were 61·36, 8·86, 0·29, and 29·49.

The "*enteric fever group*" caused 257 admissions and 25 deaths, the ratios per 1000 being 4·5 and 0·44 respectively, compared with 7·5 and 0·70 in 1918, and 3·3 and 0·37 in the pre-war quinquennium, 1910–14. Of these total admissions only 56, and of the total deaths only 14, were definitely diagnosed as "*typhoid*"; *paratyphoid A* accounting for 74 cases with one death, and paratyphoid B for one case, not fatal; the remaining 126 cases, with 10 deaths, are returned as belonging to the "enteric group." It is unfortunate, and confusing, that this expression is used for the whole group of fevers, which in previous reports had been called *enterica*, as well as, in a restricted sense, for those cases that are not definitely diagnosed as typhoid or paratyphoid A or B. Nothing approaching epidemic prevalence occurred, except at Poona, where, of 47 cases, 40 were among men attached to the military accounts department; men located over a wide area, chiefly under canvas, and in the cantonment area adjacent to the city. The majority took their meals in hotels and restaurants in Poona, the sanitary arrangements in which were difficult to control. No local source of infection was found, and no carriers were detected. At the half-yearly census of European troops, taken on Dec. 31st, 1918, only 1487 (out of 56,561) were found to be not inoculated against enteric. The admissions for dysentery (14·2 per 1000) were more numerous than in recent years; in 1918 they had been 13·8 and in the pre-war quinquennium 6·5 per 1000. Taking dysentery, colitis, and diarrhœa together, the combined admission rate was 55·5, as compared with 24·4 in 1910–14. Of 703 cases of dysentery examined, 596 were reported as amœbic and 95 as bacillary. Venereal disease, which had caused 67·8 admissions per 1000 in 1909, fell to 55·2 in 1914 and 29·1 in 1915; since then the ratio has risen year by year to 87·6 in 1919. This has occurred "in spite of every local effort on the usual lines to check the incidence of the disease." It is attributed to the long time men of the Territorial Army and garrison battalions were necessarily retained in India, "with a resulting loss of moral restraint"; also, defective lighting and want of electric fans in most barracks lead men to seek more attractive resorts in the bazaar, &c. The provision of proper lighting, with fans and anti-mosquito arrangements in barracks, might be regarded as a "local effort to check the incidence of the disease" which was not carried out by the authorities concerned.

Cholera caused only 24 admissions (0·4 per 1000), with 11 deaths (0·19 per 1000); in 1918 the ratios had been 1·0 and 0·42, and in the quinquennium, 1910–14, 0·3 and 0·14 respectively; 9 of the cases occurred at Colaba, where the disease was prevalent in the neighbourhood. There were 416 admissions to hospital for heat-stroke, with 42 deaths (7·4 and 0·74 per 1000), less than in the previous year, but far more than in the quinquennium (1·9 and 0·15 per 1000); this was partly due to retention of men in the plains during a very trying hot weather. There were 139 admissions at Lucknow (100·5 per 1000), of which 96 (with 6 deaths) were from the 3rd Garrison Battalion Bedfordshire Regiment, "a unit which contained a high proportion of elderly men, and had suffered severely from malaria and influenza in Burma. The outbreak occurred as a sequel to the move of the unit from Burma to Lucknow at the hottest time of the year, necessitated by the outbreak of hostilities on the North-West Frontier."

Pulmonary tuberculosis caused 84 admissions and 10 deaths (1·5 and 0·18 per 1000), compared with ratios of 1·8 and 0·22 in 1918, and 1·1 and 0·16 in 1910–11. For small-pox there were 173 admissions (3·1 per 1000), with 19 deaths (0·34 per 1000); in 1918 these ratios had been 1·3 and 0·2 respectively; the cases were sporadic, except at Peshawar, where there were 17, mostly in November and December. It was reported that units arriving from England were in many instances very imperfectly protected. In 15 of the 19 fatal cases it was ascertained that 4 had never been vaccinated, 9 only in infancy, 1 in infancy and re-vaccinated during the incubation period of the disease, and 1 re-vaccinated in 1915, with modified result.

The number of men invalided home was 4321, giving a ratio of 76·40, compared with 22·81 in 1910 and 7·03 in the pre-war quinquennium; the chief causes were heart disease (690), malaria (580), and debility (408). The very high and whether, in view of the posters issued by the Minister of Pensions in 1919 intimating to disabled men that during treatment, while unable to earn, they would be given adequate allowances for the support of themselves and their families, this practice would be reconsidered ?—Mr. MACPHERSON replied: I regret that the figures for which my hon. friend asks are not available. I would, however, point out that it is not the duty of the medical officers of the Ministry to certify men as fit for work, and that treatment allowances can only be authorised under the terms of the Royal Warrant when, in consequence of the treatment provided, the man is rendered unable to provide for his own support and that of his family. This is not a new principle and I am not prepared to recommend any amendment of the Warrant in this respect.

---

[1] Report of the Sanitary Commissioner with the Government of India for 1919. Calcutta: Superintendent of Government Printing. July, 1921.

MONDAY, DEC. 19TH.

Parcels of Anæsthetics Held Up.

Dr. MURRAY asked the Chancellor of the Exchequer whether he could say why it happened that three parcels of beta-eucaine arrived from Germany on the ss. *Oranje Nassau* on Nov. 4th and that the importers of these parcels were not advised of their arrival until Nov. 21st; why, when they paid on Nov. 22nd the duty demanded by His Majesty's Customs under the Safeguarding of Industries Act, they were still unable to obtain delivery of the parcels; whether he was aware that daily application were made to the Customs' parcels post department at Mount Pleasant, who were informed that the material contained in the parcels consisted of important local anæsthetics used in surgical operations and was urgently required by hospitals; why delivery was not obtained from His Majesty's Customs until Dec. 8th; and whether he proposed to take steps to obviate the continuance of such delays.—Mr. HILTON YOUNG replied: The parcels in question reached the Customs on Nov. 15th and the notice on arrival was sent to the addressees on the 18th. Duty was paid on the 22nd, but it is regretted that owing to the transfer of this parcel post work to more commodious premises which was then proceeding, a delay occurred which was unavoidable in the circumstances. This cause of delay will not recur, and the transfer will benefit importers by reason of the possibility of accelerating delivery which it will afford.

Importation of Chemicals.

Dr. MURRAY asked the Chancellor of the Exchequer whether he was aware that, owing to the absence of technical knowledge of chemicals on the part of the Customs officials ordinarily concerned with the examination of goods arriving at the various ports throughout the country, it had become the practice of His Majesty's Customs to detain all parcels of chemicals and to refuse delivery to importers on the ground that inquiries were being made: that the consequent delay, even in the case of goods not dutiable, frequently amounted to weeks; and that it had become the practice of His Majesty's Customs to ignore any interim complaints which might be made by traders as to the great inconvenience that they were put to by the consequent hold-up of business; and whether he could devise some means whereby a decision might be given on the spot in any cases of this kind which involved only an ordinary working technical knowledge of the commodities in question.—Mr. HILTON YOUNG (Financial Secretary to the Treasury) replied: In the case of chemicals entered as not liable to duty, as to which the examining Customs officer is in doubt whether duty is not chargeable under Part I. of the Safeguarding of Industries Act, it is necessary to submit a sample for expert opinion by the Government chemist, and this opinion is obtained with the least possible delay. But if the importer wishes to obtain immediate possession of the goods it is always open to him to do so on deposit of an amount sufficient to cover the duty in the event of the goods being ultimately held to be liable. As decisions are given on various substances the officers at the ports will become more experienced in deciding liability without the necessity of submitting samples, and the inconvenience complained of will diminish. I am not, however, prepared to incur the expense attendant on the appointment of expert advisers at the various ports.

UNIVERSITY OF PARIS: POST-GRADUATE COURSE IN OPHTHALMOLOGY.—Prof. F. de Lapersonne, with the assistance of Prof. F. Terrien and Drs. A. Hautant, E. Velter, P. Prelat, and Monbrun, will hold a post-graduate course in ophthalmology beginning on May 23rd, 1922. The course will include clinical teaching and practical instruction in operative and laboratory work. Lectures and practical work will be held daily in May and June, and a special certificate from the Faculty of Medicine of the University of Paris will be given to medical men who have completed the course. Medical men and students who wish to attend are asked to write to the Secretary of the Faculty of Medicine. The number admitted will be limited to 30 and the fee is Fr.150.

Medical News.

UNIVERSITY OF CAMBRIDGE.—The following degrees have been conferred:—

M.D.—B. K. T. Collins, Trinity; and J. C. Matthews, Downing.

M.B. and B.Ch.—C. H. Whittle, Queens'; W. H. Blackburn, Christ's; C. Suffern and G. D. C. Tracy, Emmanuel; and L. Cunningham, Downing.

M.B.—P. D. H. Chapman and H. A. A. Pargeter, Sidney; and N. D. Dunscombe and J. Whittingdale, Downing.

B.Ch.—G. H. Ward, Caius.

The following candidates have passed both parts of the examination in Psychological Medicine and are entitled to receive the diploma: M. A. Archdale, S. Kelly, G. A. Lilly, R. A. Noble, and W. D. Wilkins.

UNIVERSITY OF LIVERPOOL.—At examinations held recently the following candidates were successful:—

DEGREES OF M.B. AND CH.B. (HONOURS).

Class I.—J. L. Armour (distinction in Surgery and Obstetrics) and C. A. Wells (distinction in Medicine and Surgery).

Class II.—C. H. R. Carmichael (distinction in Surgery) and E. N. Chamberlain (distinction in Medicine).

FINAL EXAMINATION FOR DEGREES OF M.B. AND CH.B.

Part III.—O. A. Akjaly, J. R. Bhatia, H. R. Chibber, A. C. Crawford, Helen M. Duvall, I. S. Fox, R. A. Galway, F. G. Latham, J. F. C. McColl, Kathleen M. Platt, Gladys Rutherford, F. C. H. Sergeant, N. S. Taylor, and W. T. de V. Thomson.

Part II.—W. H. A. Dodd, G. T. Krajewski, C. B. Lewis, G. F. G. Prideaux, G. Sanders, E. R. Smith, Enid F. Stowell, A. Weisberg, and D. A. Woodeson.

Part I.—A. R. D. Adams, J. Berkson, R. W. Brookfield, T. L. Bulmer, I. Casdan, W. J. B. Chidlow, R. G. Cooke, R. L. Corlett, I. H. Davies, Hilda M. Davis, F. Earlam. F. S. Fowweather, Susan Gluck, H. Graf, J. R. Griffiths, A. J. Hawe, C. W. Healey, S. Hesselberg, Elizabeth Hunt, L. E. Johnson, F. H. Jones, A. Kefalas, T. J. Kirkpatrick, D. A. Levin, Eileen M. Lloyd, Marion R. Lunt, D. Macfarlane, Mary M. McMillan, P. Madan, P. Malpas, C. H. Owen, Eleanor M. P. Pearson, J. D. O'M. Poole, E. L. Roberts, J. Roberts (with distinction), Dorothea W. Rogers, J. A. Scott, J. F. D. Shrewsbury, E. R. Smith, J. R. A. Tallack, Dorothy A. Taylor, Elizabeth M. Theron, V. T. Thierens, H. A. Thomas, R. W. Thomas, A. Tumarkin (with distinction), E. J. Whymark, H. P. Widdup, A. G. Wilkinson, E. B. Wilkinson, and J. Williams.

DIPLOMA IN TROPICAL MEDICINE.

G. P. F. Allen (recommended for the Alan H. Milne Memorial Medal), C. R. Corfield, A. Hamid, B. W. Longhurst, G. A. Macvea, H. R. Madan, W. P. Mulligan, and S. S. Shri Kent.

UNIVERSITY OF DUBLIN, SCHOOL OF PHYSIC, TRINITY COLLEGE.—At examinations held recently the following candidates were successful:—

FINAL MEDICAL EXAMINATION.

Part I., Materia Medica and Therapeutics; Medical Jurisprudence and Hygiene; Bacteriology and Pathology.—Bernard Gluck, Francis J. O'Meara, Victor O. McCormick. Joseph A. Gaynor, and Marjorie F. Sibthorpe (all of whom passed on high marks), Benjamin W. D. Fayle, John E. McCormick, Norman E. H. P. Williams, Florine Isabel Irwin, Henry O'Donnell Burke-Gaffney, Reuben Lipschitz, Percy Samolsky, Ely G. Copeland, Johannes H. Stals, Wilfrid E. C. Wynne, Eileen Agnes Boyd, Maurice Schwartzberg, Henry M. Martin, Thomas G. Wilson, William E. Callanan, Anne D. Dockrell, Edward Harvey, Jan Hendrik Hodgman, Raymond J. G. Hyde, Lionel S. Levitt, Siegfried D. Gabbe, Asher Asherson, Robert S. McElroy, Robert L. C. Fisher, Bertha H. Lawler, Norah M. Gilcriest, and Julius Kruger.

Pathology only.—Joseph Harte and Jacobus F. van Staden.

Materia Medica and Therapeutics; Medical Jurisprudence and Hygiene.—David J. Malan, Henry C. Joly, William L. Duncan, and James J. Fitzgerald.

Medical Jurisprudence and Hygiene; Bacteriology and Pathology.—Eric C. Downer.

Part II., Medicine.—Gilbert M. Irvine, Charles Theodore de Mornet Villet, Ninian McIntire Falkiner, William A. Murphy, Cyril J. U. Murphy, Cornelis Derksen Dijkman. Minnie Alper, Joseph C. Gillespie, Theunis de Bruijn, John Lait, Francis Malone-Barrett, Albert S. Bradlaw, John R. Craig, Robert Dormer, Abraham Agranat, Vera G. M. Menary, Max W. Kaplan, Robert N. Perrott, Petrus H. S. Fouche, Margery Bouchier-Hayes, Max Elion, Gilbert Kirker, Robert A. O'Meara, and John D. Watson.

Midwifery.—Seymour G. Rainsford and Abraham Agranat (passed on high marks), Samuel G. Weldon, Petrus H. S. Fouche, Leon O. Vereneil, Hendrik Nicolas Krige, Izidore P. Myers, John C. J. McEntee, John V. Carroll, Ruth Lemon, Albert E. Phillips, Charles E. Brunton, Izak F. A. de Villiers, Leopold Stazunsky, Charlotte A. Stuart, Maurice Bewley, May E. Powell, Max W. Kaplan, James J. P. Kelly, Charles E. Ovendale, Gideon C. Malherbe, Richard Lang, Victor Robinson, George Blackall, Ruth F. Flavelle, Jacob Hofman, Minnie Alper, Dorothy A. Daly, John H. J. Stuart, Olive V.

the total deaths numbering 578,426; the highest mortality occurred in Assam (5·61 per 1000), and Central Provinces (4·46), the greatest number of deaths (121,019, equalling 2·8 per 1000) in Bengal. Contaminated water is the commonest vehicle of infection, but increasing use is made of potassium permanganate and chloride of lime for disinfecting tanks. Migration of cooly labourers and the assemblage of pilgrims, as at the Ganga Sagar *mela* in January, and at Hardwar, are also factors in causing epidemics. In Bombay Presidency 1919 was the worst year for cholera (with two exceptions, 1900 and 1912) for 20 years; famine conditions and scarcity of drinking water were responsible for this result. Small-pox was epidemic in Bengal, Madras, and the Punjab, the death ratios being 0·8, 1·0, and 0·70 per 1000 respectively; in Coorg there were 529 deaths, giving a ratio of 3·02 per 1000, and in the district of Mercara in this province the mortality was 5·90 per 1000, this being much the highest district ratio throughout India. For plague the death-rate was 0·31 per 1000, compared with 1·85 in 1918; rat destruction, attention to the storage of grain, and inoculation have been carried out systematically. The death-rate from fevers fell from 46·60 in 1918 to 22·93 in 1919, this reduction being largely due to diminution of influenza.

In the *Jails* of India, with an average population of 115,499 in 1919 (compared with 102,318 for the decennium) the constantly sick- and death-rates were 31 and 26·97, compared with 39 and 42·15 in the previous year, the corresponding ratios for the decennium having been 28·0 and 21·25. Attention is drawn to the necessity for "coördination in health administration, not, as at present, a separation into more or less water-tight compartments dealing with hospitals, sanitation, health of prisoners, &c."; what is wanted is some means of "bringing the results of research to the notice of those engaged in the application of methods."

In the section of "General Remarks" some interesting details are given as to the introduction of plague infection by shipping; a committee was appointed to deal with the subject. The conclusion arrived at was that the prevention of access of rats to ships is at present impracticable, and that efficient periodic "deratisation" should be carried out, provided that a suitable gas for fumigation is found, and that the efficient ventilation of the holds is secured. Lieut.-Col. Glen Liston, I.M.S., has devised a machine for the use of hydrocyanic gas, which is now under trial.

This report extends to 316 pages and is fully illustrated by diagrams and tables; the accuracy of the printing is almost perfect. We regret the absence of a map, such as generally provided hitherto, especially as there have been numerous changes in provincial areas and designations within recent years. The first two sections, dealing with the European and Indian armies, are contributed by the Director of Medical Services in India; and the remainder of the volume by Lieut.-Col. F. H. G. Hutchinson, I.M.S., the Sanitary Commissioner.

ACOUSTICON AIDS FOR THE DEAF.

THE electrical hearing aids for the deaf supplied by Acousticons, Ltd., of 18, Hanover-street, W., and manufactured, as we understand, in the United States, are well-made and finished. They consist, as do all electrical aids, of a transmitter and a dry cell attached by a flexible cord to a receiver; the latter may be held to the ear by a lorgnette handle, or fastened to the head by a spring-band. Five types were submitted to us; in the first a single transmitter is rigidly attached to the dry cell and intended to be held in the hand, in the second the transmitter is designed to be worn under a man's tie or a lady's blouse, is provided with a clip and is connected by a cord to the battery which is kept in the pocket or any convenient place. The third type is similar, but has two transmitters fixed rigidly together, and so gives a greater volume of sound; in the fourth type the double transmitter may be used in the same way, or may be fixed into the side of a neat black leather box, which also accommodates the battery, so that it may be used as a table instrument. The fifth type is a table instrument and has four transmitters; it is provided with a switch which disconnects two of the transmitters when desired. All the instruments are fitted with a rheostat to regulate the strength of the current, and with a switch in the receiver to shut off the current when not in use; to conserve the batteries it is most important that this should always be done. The batteries give about 40 hours' service and can then be renewed at the cost of a few shillings. The price of the instruments is naturally high; the first two with a single receiver cost 12 guineas each, the third type costs 14 guineas, and the fourth 16 guineas. We have examined these instruments and tested them on several cases of middle-ear deafness. They give a greatly increased volume of sound—those with multiple transmitters being of course the louder; they are to a considerable extent free from the annoying noises associated with telephonic apparatus; and they have a pleasant timbre with little of the disagreeable "tinny" quality sometimes heard, this being especially the case with the multiple transmitter instruments. The type described here as the fourth, which can be worn on the person or used as a table instrument, is particularly well arranged.

Electrical appliances are of small assistance in cases of nerve-deafness, but are of value in severe deafness due to middle-ear affections; patients with a moderate degree of impairment of hearing are apt to find the adventitious sounds and the quality of the timbre disagreeable, and often prefer some form of resonator. It is much to be hoped that the prejudice against all forms of hearing aid among the general public will soon disappear, for a properly fitted modern appliance is inconspicuous and helps both the patient and his friends.

THE DOCTOR IN COUNTRY LIFE.

To the Editor of THE LANCET.

SIR,—I am writing a book on various aspects of life in the country side, and I wish to include some account of the work of the country doctor, who plays such an important part in our rural life. We all know him as a good friend, often heroic, and kind and generous to our poorer neighbours. I should be very grateful if some of your readers will kindly give me references to books and articles, Government reports, &c., wherein the work of the country practitioner is summarised or explained; and if anybody should be moved to send me any personal experiences or illustrative anecdotes, either about their own work or that of men they have known, I should be greatly obliged. Of course, no names would be published except by permission of the writers.—I am, Sir, yours faithfully,

P. H. DITCHFIELD, M.A., F.S.A.,
Author of "The Parish Clerk," "Old-time Parson," &c.

Barkham Rectory, Wokingham, Dec. 18th, 1921.

THE ASSOCIATION OF CERTIFICATED BLIND MASSEURS.

To the Editor of THE LANCET.

SIR,—Will you allow me to state that it was through the untiring efforts of the late Sir Arthur Pearson, whose tragic death has aroused world-wide sympathy, that blinded soldiers and civilians were trained in the profession of massage, and to suggest that there is no way in which the medical profession can better pay lasting tribute to his memory than by helping those who have received this training to become independent. Our members are established in all parts of London and the provinces, they do not undertake the treatment of patients without the consent and advice of a registered medical practitioner, and their names and addresses can be obtained on application to

THE SECRETARY.

221-6-8, Great Portland-street, London, W. 1.
(Tel.: Langham 2542.)

THE FUTURE OF VETERINARY SCIENCE.

IN a recent address delivered at Exeter, Prof. J. Share-Jones, professor of veterinary anatomy at the University of Liverpool, claimed that the progress of veterinary science in this country had been retarded by the popular idea that its sole concern was the doctoring of sick animals. As chairman of a committee which had been addressed a question from the Government concerning the absorptive capacity of the profession, he was able to state, after inquiry, that in peace-time the Ministry of War could absorb nearly four times as many qualified veterinary sugeons as the Ministry of Agriculture, whilst an adequate public health service would require five times as many.

In 1918 Lord Haldane's Royal Commission on University Education had reported that "the modern veterinary surgeon should proceed through an exacting programme of education, a course of training as specialised and as thorough as that of the student of human medicine." The Commission were of the opinion that the future of veterinary science depended upon its adoption of methods of dealing with disease which had been worked out for human pathology; they also referred to the close association of many human and animal diseases, and the consequent necessity of joint research work.

The Ministry of Health, said Prof. Share-Jones, was the department to have principal charge of veterinary science; it was absurd that rabies should be dealt with by the Ministry of Agriculture, whilst hydrophobia was dealt with by the Ministry of Health. The veterinary profession needed men, in adequate numbers and possessing the highest possible qualifications, in order that the host of unqualified and incapable practitioners might be eliminated; veterinary science would then assume its proper position in medical science and preventive medicine.

Medico-Legal Society: Annual Dinner.—The annual dinner was held on Dec. 14th at the Holborn Restaurant, London, Mr. Justice Atkin presiding. Among the invited guests were the Lord Chief Justice, the Attorney-General, Sir William Willcox, Mr. James Berry, and Sir William Collins. The last-named, in proposing the toast of Medicine and the Law, expressed his belief that the voluntary system of hospital management would outlast any form of State control.

The late Dr. W. Keith Welsh.—The death occurred on Dec. 11th at the age of 72, at Waterlooville, where he had lived since his retirement, of W. Keith Welsh, L.R.C.P. Edin., who practised for about 40 years in Portsmouth. He was for nearly the whole of that period one of the parish medical officers, and his conscientious work and kindly manner made him very popular amongst members of friendly societies in the town; and he was esteemed by his colleagues as well as by a wide circle of friends and will be greatly missed.

Eradication of Verminous Conditions in London.—In its new General Powers Bill, which is to be submitted to Parliament in the session of 1922, the London County Council will seek additional powers for dealing with filthy and verminous articles and premises. The intention is to render more effective the powers already possessed by borough councils under the General Powers Act of 1904. Difficulty has been experienced in administering the 1904 Act, under which a sanitary authority cannot deal with verminous articles or premises unless a borough medical officer can certify that he has actually seen vermin therein. Under the Bill it will be possible for a sanitary authority to deal with such articles upon a report from a medical officer that they had been used by a verminous person. The work of cleansing or destruction will be carried out at the expense of the sanitary authority, and provision is made requiring the sanitary authority to compensate an owner who suffers unnecessary damage by reason of the exercise of the powers of the section, and also to compensate him for articles destroyed. A definition of vermin is included, and improved powers of entry are sought. The Council believes it will be more convenient to repeal all the provisions dealing with the subject in the Act of 1904 than to modify them, and the Bill will therfore contain new provisions.

The late Dr. Thomas Algernon Chapman, F.R.S.—On Dec. 17th Dr. T. A. Chapman died at Reigate, where he had lived in retirement, at the age of 79. He qualified M.D. Glasgow with honours in 1863, becoming L.R.C.S. Edin. in the same year. He held the posts of resident physician and surgeon at the Glasgow Royal Infirmary and later became interested in mental diseases. This interest led to his appointment as assistant medical officer to the Joint Counties Hospital at Abergavenny, and eventually he became medical superintendent of the County and City Asylum at Hereford. But Dr. Chapman's real interest and the source of his fame was the study of entomology. He was a distinguished Fellow of the Entomological and of the Zoological Societies, and in 1918 obtained the Fellowship of the Royal Society for his scientific work. His publications include a book on the genus *Acronycta* and its allies and many contributions to the Royal Society, the most recent of which, presented last session, include papers on an undescribed Lycænid butterfly from Cyprus and on the full grown larva of an allied species. The number of medical men who find sufficient leisure to become distinguished in other spheres is rare, and the death of Dr. Chapman removes a useful link between medicine and its sister sciences.

Corrigendum.—In the subscription list to the Wood-Hill Fund, appearing in our issue of Dec. 17th, p. 1299, Mr. G. Grey Turner, Mr. H. A. T. Fairbank, Mr. E. H. Bruce-Fox, Mr. William Wyllys, and Sir Hugh M. Rigby should have been shown as donors of ten guineas each. We regret the error.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

West London Post-Graduate College, West London Hospital, Hammersmith, W.

Wednesday, Dec. 28th.—10 A.M., Mr. MacDonald: Genito-Urinary Department.

Thursday.—2 P.M., Mr. Donald Armour: Operations.

Friday.—2 P.M., Mr. Sinclair: Surgical Out-patients.

Saturday.—10 A.M., Dr. Arthur Saunders: Medical Diseases of Children.

Daily:—10 A.M., Visit of Post-graduates to Wards. 2 P.M., In-patients, Out-patient Clinics and Operations.

Vacancies.

For further information refer to the advertisement columns.

Bath, Winsley Sanatorium.—Asst. Res. M.O. £250.

Birmingham General Hospital.—Res. M.O. £155. H.P. and H.S.

Birmingham, Rubery Hill and Hollymoor Mental Hospital.—Jun. Asst. M.O. £400.

Birmingham University.—Prof. of Anatomy. £1000.

Blackburn County Borough.—Asst. M.O.H. £600.

Bolton County Borough.—Asst. M.O.H. and School M.O. £400.

Bristol, Ministry of Pensions Hospital.—Jun. M.O. £350.

Bury Infirmary.—Jun. H.S. £150.

Cambridge, Addenbrooke's Hospital.—H.S. £130.

Canterbury, Kent and Canterbury Hospital.—Hon. Ophth. S. Also Res. M.O. £175.

Cape Town University.—Tech. Asst. in Surgery. £350. Sen. Lect. in Physics. £450.

Central London Throat and Ear Hospital, Gray's Inn-road.—Fifth Asst. S.

Chester, Cheshire County Council.—Dist. Tub. O. £600.

Colchester, Severalls Mental Hospital.—Asst. M.O. £7 7s. weekly.

Derbyshire County Council.—Sanat. Supt. £700.

Doncaster Royal Infirmary and Dispensary.—Jun. H.S. £200.

Dorchester, Dorset County Council.—Asst. M.O. £500.

Exeter, Royal Devon and Exeter Hospital.—Sen. H.S. £250. Asst. H.S. £150.

Gloucester County Mental Hospital.—Jun. A.M.O. £350.

Hertford County Hospital.—H.S. £200.

Hospital for Sick Children, Great Ormond-street.—Cas. O. £400

Kidderminster Infirmary and Children's Hospital.—H.S. £180.

Leeds Public Dispensary.—Sen. Res. M.O. £250.

Lincoln, Bracebridge Mental Hospital.—Med. Supt. £750.

Lincoln County Hospital.—Jun. H.S. £150.

Lincoln, Lindsey County Council.—Female Asst. M.O. £550.

Macclesfield General Infirmary.—Sen. H.S. £200.

Manchester, Ancoats Hospital.—Radiological Reg. £100. Res. Surg. O. £250.

Manchester Royal Infirmary.—Res. M.O. £200. Asst. M.O. and Second A.M.O. Each £100.

National Hospital for Diseases of Heart, Westmoreland-street.—Res. M.O. £150.

Norwich, Norfolk and Norwich Hospital.—H.S. £200.

Poplar Borough.—M.O. £200.

Putney Hospital.—Hon. Surg.

Royal College of Physicians, Pall Mall.—Milroy Lecturrer.

Royal Naval Medical Service.—Surg. Lieuts.

St. Peter's Hospital, Covent Garden.—Hon. V.D. Officer.

Sheffield Royal Infirmary.—Cas. O. and H.S. £150.

Shrewsbury, Royal Salop Infirmary.—H.S. £275.

Southampton Free Eye Hospital.—H.S. £150.

Southport General Infirmary.—Jun. H.S. £175.

Stoke-on-Trent County Borough.—Asst. Tub. O. £350.

The Chief Inspector of Factories, Home Office, London, S.W., announces the following vacant appointments: Dorking (Surrey), Winchcomb (Gloucester).

Births, Marriages, and Deaths.

BIRTHS.

Cowell.—On Dec. 10th, at a nursing home, the wife of Lt.-Col. E. M. Cowell, D.S.O., M.D., F.R.C.S. (R.A.M.C., T.A.), of Park-lane, Croydon, of a son.

Edwards.—On Dec. 15th, at "Rosetta," Beckenham, Kent, the wife of Major Harry Rumsey Edwards, R.A.M.C., of a son.

Mitchell.—On Dec. 12th, the wife of E. J. D. Mitchell, M.A., M.B., Weymouth-street, W., of a son.

Unwin.—On Dec. 15th, at Kingston House, Yeovil, the wife of Harold R. Unwin, F.R.C.S., of a daughter.

MARRIAGES.

Wardrop—Sutton.—On Dec. 17th, at St. Anne's Church, Highgate, J. G. Wardrop, M.D., Leamington, to Muriel, daughter of A. Sutton, Brookfield-park, N.W.

DEATHS.

Chapman.—On Dec. 17th, at Betula, Reigate, Thomas A. Chapman, M.D., F.R.S.

Cox.—On Dec. 13th, at The Limes, Cottenham, near Cambridge, Charles Hayden Cox, L.R.C.P.I., L.M., L.R.C.S.I., aged 65.

Elliott.—On Dec. 19th, after a short illness, at 24, Nicholas-street, Chester, John Elliott, M.D.Lond., F.R.C.P. Lond., in his 61st year.

Mason.—On Dec. 17th, of heart failure, at The Limes, Deal, Alfred Mason, O.B.E., M.C., L.R.C.P., aged 44.

Middleton.—On Dec. 8th, at Dorset-road, Bexhill, William Robert Colvin Middleton, M.A., M.D., C.M., D.P.H., late Medical Officer of Health of Singapore, aged 58.

Waller.—On Dec. 16th, at Bedford, Walter A. E. Waller, M.R.C.S., L.R.C.P., aged 73.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

COLLEGE LIBRARY No.

Bradshaw Lecture

ON

SUBTROPICAL ESCULENTS.

Delivered before the Royal College of Physicians of London.

BY MICHAEL C. GRABHAM, M.D. ABERD., F.R.C.P. LOND.

THE purpose of this lecture is to bring before the College knowledge acquired during a long experience of the esculents, both animal and vegetable, produced where winter does not forbid—esculents which increasing communication, rapid transit, and modern methods of preservation have made available for us in their first freshness, when the short cold days of the north have restricted the profusion of our home-grown supplies.

In the limits of one brief lecture I can only hope to touch the fringe of so great a subject, although I also hope to justify a transgression beyond the limits which have hitherto confined the subject-matter of our annual Bradshaw Commemoration.

VEGETABLE FOODS.

I propose first to deal with vegetable esculents, selecting such examples as may best illustrate the growing importance of the food, vital and accessory, with which we can supplement home production.

Custard Apples, Smooth and Reticular.—The common custard apple, *Anona cherimolia,* grows abundantly in Madeira up to 1000 ft. above sea-level, and is exported to England in ever-increasing quantities. It matures in October and is available until April; the fruit is gathered when fully developed and ripens perfectly during the three days' voyage to Europe. There are many varieties; the best are scantily reticulated and bear few seeds. The typical fruit is not met with in perfection south of Madeira, though other species, such as the squamose, are common in the Cape Verde Islands. It will not bear a long journey and the specific delicacy of flavour is completely lost by cold storage. The stony, hard, black seeds of this delicious fruit survive beneath our feet in the Trafalgar-square district of the London clay, and indicate to some extent the nature of the flora of this latitude in Eocene times.

Cruciferæ.

The principal edible species of the cruciferæ abound in all the Atlantic islands, but are not exported.

Water-cress.—Among the cruciferæ *Nasturtium officinale,* the common water-cress, occurs in every mountain stream, and is largely used as an ingredient in Spanish and Portuguese soups. A spinach of water-cress into which fragments of the fungus *Boletus edulis* have been crumbled makes a dainty and agreeable nutriment. It is held in high repute as a remedy in pulmonary disorders and in the treatment of gout and rheumatism, and I have seen marked advantage derived from its use in the latter maladies. I was informed by a Scottish landowner that the cattle feeding in meadows which were traversed by a meandering stream stocked with water-cress were entirely exempt from the rheumatism and swollen joints affecting the rest of his flocks and herds, and that they retained the immunity thus acquired when they had migrated and mixed with other stocks.

The cruciferæ are pre-eminent in the natural orders for their antiscorbutic qualities; *Cochlearia officinalis* must not escape notice in this respect.

The Mango: the Genus Citrus.

Anacardiaceæ: Mangifera Indica.—The mango, though comparatively rare in the Canary and Cape Verde Islands, is very common in Madeira, fruiting abundantly when 10 years old. The oval yellow and pink-flushed fruit, stringy in substance, abounds with a rich nectarine-tasting juice not free from a resinous or carrot-like suggestion. Though distinctly smaller and less luscious than the more highly matured West Indian fruit, the Madeira mangoes carry well and find a ready sale in London during October and November. An attractive variety of the Bombay mango has recently been imported into Madeira, which is beginning to yield abundantly a somewhat larger fruit, free from fibre, but with a flavour slightly inferior to that of the wilder sorts.

The orange, *Citrus aurantium,* is found in all the Atlantic islands, varying in quality with local circumstances and environment. As it bears transport from distant regions and is not hurt by cold storage, there is here never any lack of the orange; the importance now ascribed to its juice in averting deficiency disease and its value in the diet of quite young children have enormously increased the perennial demand and consumption of this important fruit. At one time the Argentine ant, in association with several species of coccus and lecanium, completely destroyed the orange plantations in Madeira; but a means of dealing with this terrible pest has now been established, and once more both *Citrus aurantium* and *Citrus nobiliss* (the tangerine) flourish unrestrained in the valleys of Madeira.

Lemon.—*Citrus limonium* in several varieties, common lemon, matchless in size and flavour, is found in all the Atlantic islands, but the lime is neglected.

Citron.—The Madeira citron, *Citrus medica,* has world-wide commercial importance, and is grown almost exclusively in a deep steamy valley 2000 ft. above the sea-level; it is, perhaps, the only satisfactory fruit of its kind imported into this country.

Plant Lice and Ants.

Many forms of aphis and coccus attack the Aurantiaceæ; they are mostly apterous, the males appearing for a short season; but in one species of lecanium, yearly more and more common, the female is also winged, and thus able to spread her progeny far and wide. They are all singularly dependent on the fostering care of the small Argentine ant, and are no longer formidable when this nursing is withdrawn. *In a British Association paper on the life-history of this ant* last year I showed that 40,500 ants in association with their fostered plant lice were engaged in draining a single lemon tree of its vitality. The female ant of the Argentine species undertakes none of the cares of motherhood, but after impregnation sheds her wings, issues forth with the workers, and in her apterous state continually founds new colonies. There seems to be an ebb and flow in the prevalence and fecundity of many species, both animal and vegetable, and the ebb phase has for some years limited the activity or propagation of the apterous *Aphis phylloxera vastatrix,* which, when first introduced, practically swept the vineyards of Madeira out of existence, but which is now almost negligible. So, also, some of the testacea, *Helix aspersa* and *Stenogyra decollata,* for example, are sometimes swarming and at other times hardly met with. Among plants the useful *Physalis peruviana,* the so-called Cape gooseberry, has its waxing and waning periods, and other solaceous examples are similarly liable to the same oscillation of activity.

The Vine.

The vine—commercially negligible further south in the North Atlantic—is now resuming its proper place in Madeira, being cultivated from the sea-level to 2000 ft. above; the ravages both of the Oidium leaf fungus and of the root-sucking *Phylloxera vastatrix* are well under control. I have no space to describe the methods of Madeira vine cultivation; and I have only a word to say of the wine itself. Before me are two specimens, one to illustrate the keeping qualities of this specific wine and the other carrying interesting associations. The wine of the vintage of 1792 is still in perfect order and is typical of a slowly matured Madeira wine. The second specimen is a wine which, when about 10 years old, was tasted at my table by Sir Wyville Thompson and some other members of the *Challenger* Expedition of 1878. I sent a cask of the wine in that famous ship for the specific development a sea voyage is suppose to impart.

Need for Further Deep-sea Exploration.

But the name of the *Challenger* has other references in this College, and I should be neglecting an opportunity if I failed to emphasise the need of further deep-sea and similar explorations. Another *Challenger* expedition is long overdue; knowledge has increased, methods of investigation have improved, great food-supplying areas await investigation; the fruitful results of the first expedition—for instance, the national value of the Christmas Island phosphates discovery and the disclosing of the now famous fishery near Wyville Thompson Ridge in the Faroe Channel—should suffice to stimulate the Government to permit the insignificant outlay necessary for this aspect of the public welfare. It may not be generally realised that the result of the *Challenger* Expedition of 1878 has been published in 13 huge quarto volumes, composed mainly of new matter, and that the record is yet incomplete; but it is well known that the knowledge acquired merely touches the fringe of the wealth awaiting investigation, and it is impossible to watch the course of the Danish vessel recently sent forth on deep-sea investigation without a sense of disappointment at our national lethargy.

Leguminosæ.

The better sorts of bean and pea degenerate both in size and flavour and require fresh seed after a year or two; and even then there is lacking, as in many subtropical fruits and vegetables, the full flavour of our English productions in their proper seasons after winter rest. There are under cultivation in Madeira alone probably not less than 40 invaliding ratio is ascribed chiefly to (1) the large number of elderly men, due for demobilisation, who were invalided in order to get them home before the onset of the hot weather, especially as ample shipping accommodation was available; and (2) the fact that the battalions arriving in the autumn were found to have a large number of men "suffering from disabilities detrimental to effective service in the tropics"—that is, they had not been adequately examined before leaving England.

Amongst *officers* the admissions to hospital were 1058·8 and the deaths 11·00 per 1000; the corresponding figures for 1918 had been 1344·6 and 15·17, and for the pre-war quinquennium 567·5 and 5·14. The chief diseases causing sickness were malaria (157·0), sandfly fever (69·8), influenza (54·1), and diarrhœa (51·5 per 1000). The admissions and deaths due to enterica were 8·4 and 0·87 among officers, as compared with 4·5 and 0·44 among other ranks. Amongst the *women* the admissions and deaths from all causes were 553·8 and 10·31 per 1000, compared with 603·0 and 24·98 in the previous year, and 501·3 and 7·09 in 1910–14; and amongst *children* 321·6 and 17·45; for whom in 1918 these ratios had been 432·9 and 20·20. The chief causes of illness were debility and malaria in the women, and in the children influenza, malaria, and bronchitis.

The Indian Army.

With regard to the *Indian Army* the Report states that "there has been a satisfactory decrease in the ratio of admissions for all causes as compared with 1918." The ratio was 767·5; this was certainly lower than that of 1918 (856·3), but it was higher than in either of the three previous years (1915–17), and very much above the pre-war quinquennial average (544·6). The continued high ratio was due to influenza (with its resultant debility); return of troops from Mesopotamia, Egypt, and the North-West Frontier; and enlistment of men below the best standard of physical fitness, in order to maintain the strength of troops required. Malaria (145·6), venereal affections (65·1), and respiratory diseases (56·8) were the chief causes of sickness; and pneumonia (2·88), influenza (2·63), respiratory diseases (1·31), and pulmonary tubercle (1·08) the most frequent causes of death; the total mortality being 11·94 per 1000. The large stations showing highest admission and mortality ratios were Bombay (1701·2 and 24·85), and Peshawar (1545·2 and 36·61). There was a very notable reduction in the enteric incidence and mortality (0·40 and 0·06 per 1000), compared with 1918 (0·80 and 0·28) and with the pre-war quinquennium (2·0 and 0·38); nowhere was there any epidemic prevalence. On the other hand, the grouped diseases, dysentery, colitis, and diarrhœa, caused 65·9 admissions per 1000, more than in 1918 (58·4), and nearly double the ratio for 1910–14 (33·5); the mortality was 0·30, compared with 0·45 in 1918 and 0·14 in 1910–14. Cholera was epidemic in the Punjab and affected the troops on active service at Peshawar and in the Khyber; excluding these there were 134 admissions and 77 deaths in the garrison of India (0·60 and 0·31 per 1000). There were no outbreaks of importance except at Kamptee (where 19 cases occurred, traced to contaminated well water), and Agra (21 cases) where a hospital cook spent his spare time at his village nursing a child with cholera. Pneumonia still causes more deaths (661) among Indian troops than any other disease, but was considerably less fatal than in 1918 (2·88 compared with 6·02), though more so than in the quinquennium (1·05). On the other hand, pulmonary tuberculosis caused 219 deaths (1·08 per 1000), compared with 0·65 in 1918 and 0·32 in 1915; for Gurkhas the admissions and deaths were 5·6 and 2·73, and for the rest of the army 3·9 and 0·91 per 1000. Plague caused only 31 admissions and 20 deaths (0·1 and 0·09 per 1000). For relapsing fever there were 141 admissions and 11 deaths, giving ratios of 0·60 and 0·05, as compared with 1·9 and 0·20 in the previous year. In the Report for 1918 attention had been drawn to the fact that Secunderabad did not appear among the ten most malarious stations in India; the fever admission ratio was 141·1 per 1000, compared with 518·1 in the previous year; this was considered to have been the result of drainage work that had been carried out and the substitution of dry for wet cultivation. Although malaria is still the chief cause of admission to hospital in India as a whole, the incidence at this station has declined still further to 56·5 per 1000; this is a striking instance of the true economy that results from expenditure in adopting the necessary preventive measures. At Peshawar, however, there was an increased incidence in spite of vigorous efforts in this direction; the admission ratio was 515·8 per 1000 (compared with 135·2 in 1918). There is a highly infected bazaar population, and the open earth water channels are badly graded. The rainfall was excessive during the malarial season, and there was a lack of mosquito-proof doors and windows in barracks; mosquito nets were provided (but perhaps not used). At 35 hospitals throughout the country attempts were made to distinguish between fresh cases and relapses; out of 11,388 fresh cases, 15·93 per cent. were of the benign tertian type, 18·48 were malignant, 1·83 quartan, 0·53 mixed, and 33·23 "clinical"; among 4082 relapses these percentages were 44·14, 18·0, 0·9, 0·39, and 36·57 respectively. Sandfly fever caused 3081 admissions (13·4 per 1000), with no deaths; all these cases occurred in the Northern Army (except 43), the respective ratios for the Northern and Southern Armies being 23·4 and 0·4; at Peshawar the ratio was 154·5, at Fort Lockhart 200·0, and at Agra 209·9 per 1000. Pyrexia of uncertain origin, for which 34·9 admissions and 0·13 deaths per 1000 had been registered in the quinquennium, 1910–14, has now fallen to 2·3 admissions, with no death; and it is hoped that it will "soon become negligible as a diagnosis in hospital." There were 94 admissions for dengue, 89 of which occurred at Rangoon; in the preceding year there had been 241 admissions, and of these 126 at the same station; no remarks are made as to this obscure, but interesting, disease; there were no deaths. For the enteric group there was a notable reduction both in admissions, which were 101 (0·4 per 1000), and deaths (14, or 0·06 per 1000), the corresponding ratios for 1918 having been 0·8 and 0·28, and for the pre-war quinquennium, 2·0 and 0·38 per 1000. No outbreaks occurred of any importance. On the other hand, for the group of intestinal diseases (dysentery, colitis, and diarrhœa) there were 15,138 admissions (65·9) and 69 deaths (0·30 per 1000), compared with corresponding ratios of 58·4 and 0·45 in 1918, and 33·5 and 0·14 for 1910–14.

A most regrettable feature in the health statistics of the native troops is the enormous increase in *Venereal Diseases* during recent years. In the report of the Sanitary Commissioner for 1899 a table was given of the venereal incidence since 1877, the earliest year for which statistics were available; the admission ratio in that year was 26·7 per 1000; in the decennium 1889–98 it averaged 38·1; in 1897–1906 the average was 30·5; in 1905–14 it was 15·6, having fallen to 12·6 in 1913. Since that year the successive ratios have been 15·6, 34·3, 40·1, 45·0, 53·1, and in 1919, 65·3. The Sanitary Commissioner draws attention to this table as showing "the steady increase in the venereal admission rate which has taken place since the first year of the great war." The epithet "steady" does not appear to be quite the *mot juste* for this (over) 400 per cent. increase on the pre-war prevalence of these affections. Cholera was epidemic in the Punjab during June and July, but did not seriously affect the Indian troops, except those on active service outside India. There were 134 cases and 77 deaths (0·6 and 0·31 per 1000) in the Indian garrison; Agra (21 cases, all in September) and Kamptee (19, all in June) were the stations that suffered most.

Pneumonia, with 12·8 admissions and 2·88 deaths per 1000 (some probably due to influenza) is still the most frequent cause of death in the Indian Army; but shows considerable improvement compared with 1918, when the ratios had been 19·6 and 6·02; in the pre-war period (1910–14) these ratios had been 7·7 and 1·05. Pulmonary tuberculosis, on the other hand, was both more frequent and more fatal than in recent years; the admissions, which for 1915 to 1918 had been in ratios of 2·8, 2·8, 2·9, and 2·5 per 1000, rose to 4·0; and the deaths, which had been 0·32, 0·42, 0·63, and 0·65, rose to 1·08 per 1000. Very high admission rates were recorded at Ahmednagar (18·6) and Benares (12·3). Gurkha troops as usual suffered most, their admission and death ratios being 5·6 and 2·73, compared with 3·9 and 0·91 for the rest of the Native Army.

The weather conditions are summarised in the section dealing with the health of the general population. For the plains of India as a whole the rainfall was 4 in. above the average, the only areas having marked deficiency being the Bay Islands, Assam, Baluchistan, and North Hyderabad.

The Health of the General Population.

Owing to the heavy influenza mortality the birth-rate fell from 37·85 (the quinquennial mean) and 35·35 (in 1918) to 30·21 per 1000; but it is acknowledged that registration is at fault, especially with regard to female births. The death-rate was 35·87, compared with 62·46 in 1918 and 36·81 in the quinquennium, 1914–18; the highest ratios were recorded in Assam (50·09), Central Provinces (43·24), and Delhi (42·00); the lowest in Madras Presidency (27·2), and the Punjab (28·31). The infant mortality varied between 17·6 and 17·7 in the North-West Frontier Province and Punjab and 32·9 in Madras city, 35·8 in Calcutta, and 65·3 in the city of Bombay. Tetanus neonatorum was prevalent in many towns and districts; much is being done, however, in the training of native midwives and the provision of maternity and child welfare centres, as well as in the establishment of coöperative dairies under skilled supervision.

The general population suffered more from cholera, small-pox, and diarrhœal diseases than in the previous year, the death ratios under these three headings being 2·43, 0·57, and 1·22, as compared with 2·35, 0·30, and 1·16 in 1918. The increase in cholera prevailed throughout the country.

come) reports the presence of the tree in abundance and vigorous condition 7000 ft. above sea-level in those scarcely explored regions. To those who do not habitually drink it coffee may prove an effective medicine; it is a valuable adjunct in the treatment of intermittent fevers, it relieves asthma, and it assists in overcoming the effects of alcohol or opium.

Compositæ.

The Jerusalem artichoke, *Helianthus tuberosus*, grows in Madeira with the same weedy profusion as in England and will profitably occupy waste ground with little care or cultivation. Artichokes (originally Brazilian) yield a heavy crop, and the interest just now attaching to the tubers has reference to the presence in their abundant tubercles of 12 or 14 per cent. of inulin, a substance akin to starch, but convertible by appropriate treatment into fructose—the sweetest of all sugars. I learned the nutritive and sustaining value of the artichoke in the second year of the war, when our reserves of food were exhausted and we had to devise or improvise new methods of sustaining life. I soon found out the value of the artichoke, then growing in small plots of waste land in my mountain home. Three or four of the tubercles were boiled into an imperfect purée, to which I added a handful of the succulent roots of *Oxalis purpurea* and a little salt. Meanwhile some strips of pumpkin food were boiled with three or four ounces of fat until the latter was emulsified or saponified; during the process chopped cabbage leaf, water-cress, or a few chestnuts were mixed in. When the cooking was nearly finished I crumbled into the mixture small pieces of half a dozen large boletus fungi. Three famished men were then fed sparingly on this potent food and regaled after two hours more copiously; and on the strength of this meal they worked nearly all day with well-sustained energy. During the stress of threatened starvation we discovered the unsuspected value of many a neglected esculent, and we also became conscious of the excesses of our diet in normal times. I made a point sometimes of interrupting a hungry man in his voracious consumption of a bulky meal to find, after half an hour, that appetite had been completely satisfied and that the remaining portion of his food would merely have taxed his gastric powers for purposes of elimination and rejection.

Convolvulaceæ.

Batatas edulis is cultivated in all the Atlantic islands in great profusion. The sweet potato is the foundation food of the Madeira peasantry and yields crop after crop freely with no restriction of season; but there is no storage or overplus for exportation either in Madeira or the Canaries. The tubers vary in weight from three or four ounces upwards, and their size relates in a great measure to the space allotted to the trailing or climbing growth of the stem, which, when unrestrained, will yield 25 to 30 lb. weight of potatoes. A man will do a heavy day's work on a sufficiency of plain boiled "batatas," but owing to their high percentage of starch the latter require to be supplemented occasionally with food of greater nitrogenous value. In the Azores the sweet potato is grown on a larger scale and is found capable of yielding a high percentage of alcohol; it has been estimated that tubers having 25 per cent. starch will yield 38 gallons of spirit per ton. The spirit thus extracted is largely used in the treatment of the wines of Portugal. A reliable analysis of sweet potatoes shows the main constituents as albumin 8·7, fatty oils 0·7, starch 80·3 per cent. from material dried at 212°F., and it has been found that three tons of starch possessing a high commercial value can be made from 12 tons of sweet potatoes, leaving a rich residue suitable for cattle food. It would thus be difficult in many respects to overrate the esculent value of this interesting convolvulus.

Solanaceæ.

Tomato (Lycopersicum) farming has now become an important industry, and it is difficult to cope with the growing demand of the European markets. Forty years ago the British supply was limited to the summer produce of our own gardens and tomato houses, and no general or perennial demand had developed. Several forms have long been naturalised in all the Atlantic islands and are to be found semi-wild in every district. This is especially the case with the wild tomato, *L. cerasiforme*, an excellent culinary example growing in every waste place perennially. In St. Jajo (Cape Verde Islands) whole mountain tracts are covered for miles with matted beds of this variety laden with its brilliant fruit, a potential wealth yet to be turned to account. Quite recently the Italians have succeeded in extracting from tomato seeds an oil suitable for soap-making. The Portuguese preserve the tomato for months in perfect freshness, entire in brine or coarse salt; preserved in this manner it must have been at my suggestion of priceless benefit as an antiscorbutic to Nares in his long and adventurous southern expedition.

Potato.—The potato, *Solanum tuberosum*, is cultivated at all seasons both in Madeira and the Canaries at all elevations, and forms an important portion of the food of the whole population, besides yielding an overplus to northern markets as new potatoes in the early spring months. The potato, though not a perfect nutrient, is believed to yield a greater bulk of sustenance per acre than any other cultivated vegetable; no other vegetable esculent is considered so essential an accompaniment to our daily meals.

Melon Pear.—The interesting *Solanum guatamelense* was brought to Madeira 30 years ago; it became well established under the fanciful name of melon pear. It bears pallid, yellow, somewhat insipid fruit as large as that of the cyphomandra, and has become the prey of the Argentine ant, in association with the *Coccus hemisphericus* of the Azores.

Cape Gooseberry.—*Physalis peruviana* is found as a weed in every garden from the sea-level to 3000 ft. above. Of the abundant fruit not one-tenth is collected, though there is an unfailing demand abroad for the Cape gooseberry jam yielded by these wholesome berries.

Lauraceæ.

Alligator Pear.—*Persea gratissima*, the avocado or alligator pear, with its thick butyraceous substance (the midshipman's butter of other days) is an excellent fruit, creamy, rich and nutty in flavour, largely eaten also as a vegetable in many forms. The pear softens in ripening four or five days after picking, and thus arrives in perfection for sale in London during the late autumn. I have sent abundant seed of our wild indigenous *Persea indica* far and wide with the view of increasing by grafting the range of the alligator pear in climates with temperature variations greater than those of Madeira. The protein content of the fruit is 2 per cent. and the fat 15 per cent.

Cannaceæ.

The famous Madeira arrowroot is grown chiefly from *Curcuma leucorhiza* and has a high commercial value. The yield is important and the quality of first-rate excellence. There is no other starch comparable in specific gravity or nutrient value to this sort when well cleaned and prepared.

Musaceæ.

Banana.—Of the many varieties of banana the Atlantic islands mainly cultivate *Musa cavendishii* both for export and home use. This fruit is brought to all the European markets, both from Madeira and from the Canary islands, and is greatly superior in taste and quality to the larger, coarser, and more insipid fruit imported from Costa Rica and the West Indies and sold in every London street on costermongers' barrows.

A far superior fruit is yielded by another species, *M. sapientum*, much cultivated in Madeira for home use but taking quite two years to mature, and known elsewhere as the silver banana or, as Sir D. Morris tells me, the apple banana. The tree grows quite 30 ft. high and is liable to destruction by high winds; the fruit requires tender handling in packing if exported. During the war the entire crop was needed locally, and in any case there were no steamers available to convey supplies away, but normally both Madeira and the Canaries yield a heavy overplus, mainly of *M. cavendishii*, which has a well-recognised value in London. Though the banana flowers are apparently perfect and their pollen abundant no seed has been known to develop through dissemination by bees. A recent analysis gives the food value of the average banana as protein 1·3 per cent., fat 0·6 per cent., total carbohydrates 22, and the tremendous importance of the fruit in our national feeding is now fully recognised, the better sorts preserving a very exquisite flavour.

The banana has spread to the masses of our people while retaining its place on the dessert table of the rich. In my early days bananas were only known in London as a curiosity with no suspicion of their great nutrient value; and for some years later they were quite unsaleable while our English summer fruits lasted. Fifty years ago the total value of fruit of all kinds exported from Jamaica was only £720; this small sum was the commencement of a banana trade which to-day is valued at a million and a half pounds sterling and is constantly expanding as the demand grows. The substantial volumes which have been written on the banana have by no means exhausted the description of the attributes and uses of the plant apart from the food value of its fruit.

Bromeliaceæ.

Pineapple.—*Ananassa sativa* will grow wild in most of the Atlantic islands, but needs all the care, selection, and treatment which have brought the fruit to perfection in the western islands; there, sun-ripened with scientific precision and methods of stifling and retarding, its appearance is made to coincide with the season of greatest demand in London and elsewhere.

Liliaceæ.

Onion.—*Allium cepa*, the common onion, is cultivated in all the islands and exported in fabulous quantity. The size and quality obtained in Madeira can hardly be surpassed; I once had a dozen bulbs presented to me, of which one weighed 4 lb., three others more than 3 lb., and the whole

AN IMPROVED VARNISH RAT-TRAP.

THE device of catching rats by putting down stiff boards smeared with lithographic varnish, with bait in the centre and foot-hold round the outer edges, originated, we believe, with Dr. W. J. Howarth, M.O.H. for the City of London. Dr. F. W. Alexander, M.O.H. for the borough of Poplar, informs us that one of his inspectors has improved this device by cutting a hole in the centre of the board with foot-hold round the hole and baits at the outer edge. This method of adapting the boards to surround the rat-holes has the advantage that the rats cannot avoid the boards, nor can they do so when, the rat-hole being against a wall, the hole in the board is made at the side instead of in the middle of the board.

BIRMINGHAM NERVE HOSPITAL: ANNUAL REPORT.

THIS is a self-supporting charity. The accounts show a gain of £180 on the year's work and an accumulated surplus of £126. New patients numbered 3101, against 2601 in the previous year, and the attendances were 26,421, against 23,288. The departments of electricity and massage have been specially successful and are to be extended and developed to meet the increasing demands. In moving the adoption of the report the Lord Mayor (Alderman David Davis) said that the hospital had been faced with exceptional difficulties from its inception. These had not yet been removed, and he would have been glad to be able to congratulate the governors upon the fact that the medical profession had offered their gratuitous services as they did to all the other hospitals. They must hope that the time was not far distant when they would receive from the medical profession that recognition to which he thought their work entitled them. During the past year the hospital had had arduous duties to perform, and enormous success had attended their efforts. The time must be rapidly approaching when a different feeling would exist towards new hospitals. If the Nerve Hospital had been doing work similar to that already carried out by other hospitals, then it might be urged that they were overlapping and there was no necessity for their hospital. But they were doing new work and relieving distress and suffering to an extent other hospitals had not yet recognised. He congratulated the governors on their financial position and wished them all success. Mr. Joseph Ansell said that many difficulties had disappeared. The need for such a hospital had been shown again and again, and he was hopeful that at the forthcoming conference any possible difficulties which at present existed between the medical profession and the hospital would disappear. Sir George Bean was elected president for the ensuing year.

THE GOVERNMENT OF INDIA AND INDIGENOUS MEDICINE.

A STATEMENT has been issued by the Government of India defining the position of indigenous medicine in the United Provinces of Agra and Oudh as regards State aid. The Ayurvedic and Unani systems of medicine are still widely popular in this province, and the policy of the Government is to help in the extension to the poor of all kinds of medical relief, including the indigenous systems of medicine; for the encouragement of the latter they included a sum of Rs.25,000 in the current year's budget. The step was in part experimental and the Government have not yet come to a final decision as to the best methods of affording financial assistance. It is believed, however, that the following methods are likely to be most fruitful: (1) To give grants to local bodies to establish travelling or stationary Ayurvedic or Unani dispensaries; (2) to give grants to existing Ayurvedic or Unani dispensaries provided that they are controlled by influential managing committees; and (3) to give grants to existing institutions for the training of Vaids and Hakins subject to the same proviso. The question of the management of Ayurvedic and Unani dispensaries maintained by local bodies is not free from difficulty. The ordinary medical staff of the district will not be available for the purpose, and the Government are of opinion that the supervision will be best exercised through health committees of the local bodies concerned. As regards grants to private institutions, no definite rule can be laid down, but before a grant is made the Government will require proof that the managing committee is influential and that the control exercised is adequate. The grants to local bodies have been allotted in most cases on the principle of giving three-fourths of the amount required for the maintenance of the dispensaries which the local bodies propose to establish, and will not actually be granted unless the local bodies agree to provide one-fourth of the actual annual expenses. In future years the Government will insist on local bodies bearing a more substantial portion of the burden. In addition to Rs.25,000 distributed to various centres a sum of Rs.30,000 has also been sanctioned for the Ayurvedic College established at Hardwar.

CRIMINAL ABORTION.

AT a recent inquest concerning a woman who died of acute general peritonitis consequent upon abortion and septic infection of the womb, Dr. F. J. Waldo, J.P., coroner for the City of London and Borough of Southwark, stated that criminal abortion had become increasingly common since the war. The dread of large families was great among many women, and habitual abortionists abounded. It behoved the police to be on the watch. Conflicting evidence, he added, had been given in the course of that particular inquest, and he trusted that the police would make good use of the clues provided. The jury deemed the evidence insufficient to show how infection was brought about.

THE HOSPITAL STAFF DISPUTE.

THE Metropolitan District Committee of the National Federation of General Workers has recommended all members of trade unions to cease subscribing to London hospitals until these have granted trade-union rates of wages to their staffs. An agreement arrived at by arbitration in July, 1920, between a group of seven hospitals and the Federation fixed the minimum wage of £3, including food, for a week of 48 hours, and it appears that most of these hospitals have given notice to withdraw from the agreement at the end of the present year. Freedom of action is the reason given for this course, and the denunciation of the award does not necessarily imply the intention on the part of hospital authorities either to increase the hours or to diminish the remuneration of their staff. The matter is obviously one for the British Hospitals' Association and the Workers' Federation to decide by collaboration. Whatever basis of charity may still lie at the root of the voluntary hospital system, there can be no intention on the part of any hospital committees, as employers of labour, to deal with their staffs otherwise than they would do in an ordinary commercial undertaking.

CHESS AND PROGNOSIS.

CAPABLANCA'S admirable treatise on "Chess Fundamentals" (London: G. Bell and Sons, Ltd., 1921, pp. 246, 10*s.* 6*d.*) will appeal to numbers of medical men and women who find their pastime in chess and who will welcome a companion volume to "My Chess Career." The manual may have a deeper interest to the student of medicine for, in setting out the best way of arriving at an end-result, it helps to throw light on that difficult game of prognosis which resembles in so many particulars a hard-fought game of chess. In medicine as in chess prognosis depends on many factors, some of them under the player's control, some not. Nature and the other fellow are both apt to find out the player's weak points. Capablanca's method of teaching is to take the end-game play when only a few pieces remain on the board, and to show the inevitable or what may be called the classical endings, when, for instance, knight and bishop can only mate the widowed king in one corner of the board just as a chronic renal or heart case may *carry on indefinitely* until cornered by a *final attack* of pneumonia or influenza. From simple end-games the strategist works back to the tactics of the middle-game with more pieces on the board and many complicating factors at issue, and leads up to the general theory of direct attack en masse or for the cutting off of particular pieces from the scene of action. The whole is a pretty analysis of a complicated game, which holds the reader as only an expert completely conversant with his subject can do.

THE LANCET: SUBSCRIPTION RATES.

INLAND	One Year	£2	2	0
	Six Months	1	1	0
	Three Months	0	10	6
ABROAD	One Year	£2	10	0
	Six Months	1	5	0
	Three Months	0	12	6

Subscriptions may commence at any time and are payable in advance. Cheques and P.O.'s (crossed "London County Westminster and Parr's Bank, Covent Garden Branch") should be made payable to THE MANAGER, THE LANCET Offices, 423, Strand, London, W.C. 2.

the chief town of Madeira, is named from the prevalence in the neighbourhood of this potent herb.

Many other species of Scombridæ also abound in East Atlantic waters. Among them is *Lepidopus caudatus*, now classed among the Trichiuridæ—a truly subtropical fish of wide distribution—known occasionally even as far north as our own southern coasts, and here called the scabbard-fish. In New Zealand it is known and esteemed as the frost-fish. The lepidopus has a band-like body, black, without scales; taken at Madeira at all seasons, it is with the tunny the mainstay of our market supplies. It grows to a length of about 6 ft. and rarely exceeds 7 or 8 lb. in weight. Though found at all depths, the lepidopus in the slender structure of its bones and other respects must be considered a deep-sea fish; its rapacious character is indicated by its formidable dentition. The flesh of no other fish is so serviceable for the table as regards variety of cooking.

Sherny.—I select the *Polyprion cernium* as typical of the highly important food-yielding order of Serranidæ. This *species is known as the wreck fish, from its habit of accompanying* floating wood, attracted thus by the small marine food species generally associated with such objects. Known as the shern or sherny, the fish has a great geographical range, and without following it into the Pacific we find it throughout the Atlantic Ocean, and even also in the Mediterranean at the present day, though there is no trace of the species in that sea in the writings of the ancient Greek and Roman naturalists. It abounds in subtropical waters and in Madeira, where it seems to occupy the place of the familiar Mediterranean *Sciæna aquila*, it is one of the commonest and best known fishes in the market, esteemed for its white flesh and substantial nutriment, though lacking any particular excellence of flavour. Possessing a high degree of muscular irritability, this fish is better for being kept quite 24 hours before boiling. The pulsation of the sherny's heart is maintained for some hours after every other sign of life has ceased—quite six hours, in my experience, when the organ has been laid open to view—and the fishermen affirm that cardiac movements sometimes continue for two days, though you cannot revive them when once they have ceased. Some of the sharks show the same apparent survival of cardiac life or motion, for I have held in my hand the beating heart of *Zygæna malleus* for some minutes after the organ had been severed from a recently captured fish. The sherny of these latitudes is only captured by the hook, and though shoals of small fishes weighing from 5 to 20 lb. are often to be taken near the surface, the proper home of the full-grown adult is in the deep open abyss where, weighing from 30 to 100 lb. or more, it is taken at the enormous depth of 2000 to 2500 ft. or even deeper. Coming up from a depth so stupendous the fish becomes so distended with gas, expanding upon the removal of the vast pressure below, that it rises to the surface, not indeed dead, but wholly powerless, in a sort of rigid cataleptic spasm. The stomach is usually inverted and protruded into or through the mouth, and its eyes forced far out of their sockets. Its life-history, rate of growth, food, and the circumstances which determine its descent from the warm surface water into the cold depths, and the means necessary for securing and utilising this great source of valuable food, are problems awaiting solution. In general character and appearance the sherny is a plain, dull-coloured unshapely fish, with a capacious gape and enormous head, showing a clear generic affinity to Serranus, but its fascinating anatomical details are beside the province of this lecture.

Market Varieties.

Distinguished ichthyologists have wondered at the variety, abundance, and colouring of the southern fish markets. There are no flat fish, and the common members of the cod-fish tribe, which so largely fill our stalls in England, are usually represented only by one subordinate species of the tribe, the Mediterranean phycis. Many of the most useful of the fish esculents are present throughout the year, though more abundant in spring and early summer; among them two species of Clupea, the *Caranx trachurus*, the familiar Zeus or John Dory, and the appreciated red mullet; but the seasons are marked by the prevalence and predominance of successive forms, which month by month vary the perennial supply. The red mullet is taken abundantly at all seasons in shallow water, in traps made of cane or wicker-work without any bait, into which the fish aimlessly wander. I once tried to augment their capture by suspending a few luminously painted shells in the traps to entice them, but these experiments were entirely vitiated by the intrusion of unwelcome visitors—octopus and conger—which, attracted by the unusual phosphorescent glow, entered and devoured the rightful occupants of my cages.

An Unexplored Food Reserve.

The impression left after contemplating our fish markets and noting the patient and primitive methods employed in capture is that we have in these southern waters a reserve and wealth of food which, in the progress of investigation, will eventually be made to minister to the needs of many regions now beyond the narrow limits of its application. And when we remember the great depth of the oceans and that plants may live and function three or four thousand feet below the surface, and moreover that animals are found at every depth, we may truly conclude that the total quantity of living matter in the sea greatly exceeds that on the land surface of the earth. The whole subject of these super-equatorial marine food resources abounds with both economic and biological interest. The surface plankton has yet to be explored; we have in these abundant surface foods a key to the welfare and maintenance of life in the depths; and it is not unusual to meet in their early stages crustacean and other species which, bred and born on the surface, *disappear and are not afterwards known in their* maturity in these waters. The globigerinous ooze on the surface below also bears evidence of the perpetual rain of food descending from above. Much of this surface organic matter is, doubtless, intercepted and consumed in its fall, but far more either reaches the bottom or is actually dissolved in the sea water and becomes thus a tangible source of deep-sea food. Nevertheless, the fat robust condition in which our large deep-sea fish arrive at the surface when captured, and the numbers in which we know them to abound, suggest the nutriment available in these abysses.

With the desire of knowing something more of deep-sea life and nutriment I have recently been sinking some large, closely woven wicker-work traps a couple of miles out at sea S.E. of Madeira in water about 1000 ft. deep. The traps are let down with stout cords buoyed all the way down at intervals with large cork floats which ease the labour of hauling in. Barnacles and other creatures soon attach themselves to the cork floats, and thus show that life is not absent in any stage of this sea depth. The traps are baited with some highly pungent decomposing animal matter, and are drawn up every 6 or 12 hours for examination. If the trap has rested on the smooth Atlantic globigerinous ooze, where—as they would be exposed to the vigilant monsters in search of food—the smaller creatures do not venture, the take is negligible; whereas, if the bottom is rocky or near some stony ledge, there seems to be an unfailing supply of well-nourished and tempting prawns (*Pandalus*) and Amphionidæ. The prawns, like some of the larger deep-sea fish I have been describing, do not survive their transference to the surface, but arrive dazed or dead. Some of them escape from the traps in the process of hauling in, but float to the surface dazed and helpless with the destructive expansion already noticed.

The Sea Bottom.

The condition of the sea bottom is not less mysterious than the life-history and food of its occupants, and occasionally we know it to be subject to change and disruptive commotion. It was my good fortune to observe the occurrence of one such commotion. I was observing at that time the strength and variations of the electrical so-called earth-currents which affect our deep-sea cables, and which, sometimes weak and sometimes active, are never entirely absent. My hope was to establish a definite relation between these submarine indications and the earth tremors registered by seismographic observation, and thus render it possible not merely to record but to predict an earthquake or a threat of earthquake in a given locality. On this occasion an earthquake of moderate intensity actually happened, shaking down great masses of rock and generating a surface wave of sea water of considerable magnitude. But the cable currents were present in great excitement quite three days before any sign of coming commotion could have effected an instrument of vibration. The cable under observation happened to lie in the path of commotion and was destroyed by the submarine disruption. It was the accident of the earthquake locality coinciding with the path of the well-marked varieties of the common French or kidney bean, *Phaseolus vulgaris*. The climbing sorts flourish in the summer season, but the dwarf kinds produce crop after crop perennially and contribute largely to British and continental markets for green vegetable food in the winter months.

The Soya bean was unknown in these regions until, in 1910, I introduced an important variety of *Glycine hispida* from Portugal. The plants have yielded their small almost round bean copiously and can be relied upon for both as a spring and autumn crop; but the species is not fully acclimatised and has suffered from some degree of hybridisation which, in spite of the power of self-fertilisation the plant possesses, the bees of Madeira have managed to effect.

The American estimate of the exceptional position held by the Soya bean is thus stated by Osborne and Mendel: "The Soya bean is probably the only seed yet investigated which contains both the water-soluble, and in a limited quantity, the fat-soluble, unidentified dietetic essentials known as vitamins: and this fact, taken in conjunction with the high physiological value of their protein, lends an unique significance to the use of this esculent as food."

The practical application of the Soya bean in a variety of cooking is very extensive and the sustaining quality is very great, whether the bean is used alone or as an adjunct. At my own table I have used the bean either as a soup purée or as a most agreeable mush to serve with fish or meat of any kind with much satisfaction. The so-called Soya milk has too much of its own specific taste for use in tea, but is excellent and creamy in coffee, and to replace milk in pastry. As human or cattle food, fertiliser, or source of vegetable oil, the Soya bean plant is an esculent of the highest economic value, and I hope to establish it shortly in the rich and extensive lands around Lake Tsana in Abyssinia, where, 7000 ft. above the sea, in true subtropical environment and in the absence of allied species and liability to hybridisation, it will become a food resource of first-rate importance. Records show that the Soya bean was cultivated and esteemed in China 5000 years ago, but only in modern times has exact knowledge of its worth been obtained.

I cannot leave the leguminosæ without a reference to the two aspects of their estimated value met with in accessible literature. Burton, in his fascinating treatise on diet and melancholy, dismisses the entire tribe with one laconic comment, "All pulse are naught." But in the charming legend of the Jewish captives who were to be fed and fattened for presentation to the king, but were allowed 10 days' experience on pulse and water alone, the probationers in that short period appeared "fairer and . . . . fatter in flesh than all the youths which did eat of the king's meat." The pulse and water diet seems to have been continued for three years without, in those primitive times, developing any of the deficiency diseases we now dread from such restrictions. I always thought that the potent pulse of Nebuchadnezzar might have referred to *Ervum lens*—the widely distributed lentil, the favourite pulse of super-equatorial regions—but there is conflict of opinion on the matter; and my learned friend who presides over the Royal Gardens at Kew considers that the prevalent *Phaseolus radiatus*, found everywhere in the East, may with greater probability be regarded as the food of the Jewish captives.

Amygdalaceæ, Rosaceæ, and Pomaceæ.

The peach, *Amygdalus persica*, may be said to flourish too well in Madeira, for its cultivation by the propagation of good sorts and eradication of the self-sown, worthless, hard-fleshed seedlings, is thus sadly neglected. Perennially green, in all cases it is grown in the standard form, coming into flower about Christmas or earlier, and ripening from July to September. The same remarks apply both to the nectarine and apricot, several kinds of which produce enormous crops of hard, poor fruit in the absence of selection or cultivation. The almond flourishes especially well in the island La Palma of the Canaries, where whole deep valleys are devoted to it. The plum, *Prunus domestica*, and the cherry, *Cerasus avium*, provide abundant crops.

The strawberry, *Fragaria vesca*, occurs in every variety, both wild and cultivated, in Madeira, though not further south. It begins to be abundant in April and yields heavily until September, never being entirely absent.

Of the Pomaceæ, *Pyrus communis*, the common pear, is abundant, but the fruit, even of the best sorts, is inferior. *Pyrus malus*, the apple, is grown in many kinds in Madeira and the Canaries, but further south rarely seen. Quince, the common cydonia, thrives in all the islands and is preserved by the Portuguese as an excellent marmalade. *Mespilus germanica*, the common medlar, is found only in Madeira, and yields excellent fruit, which, however, is not greatly esteemed. *Eriobotrya japonica*, the loquat or Japanese medlar, a more important fruit, has become extremely common in Madeira, but not further south; its acidulous amber-coloured fruit, which is produced from February to May in great quantities, should be available as a cheap and agreeable comestible in the fruit-vacant months of the early English spring.

Among the Myrtaceæ, the guava (Psidium) is found principally in Madeira. The fruit is largely used like apples for culinary purposes and for dessert, but does not now exist in sufficient quantity for export on account of the ravages of the Argentine ant. The white fruit is far superior to the red and smaller variety. *P. littorale* and *P. cattleyana* flourish everywhere and yield an agreeable little fruit, sometimes twice a year.

Passifloraceæ.

Among all the gorgeous varieties of passion flower which adorn the Madeira gardens two only need here be mentioned. The abundant *Passiflora edulis* has purple fruit the size of a small hen's egg with orange-coloured pulp and an agreeable raspberry-like flavour; it was hardly known in the Canaries a few years ago. *Passiflora lowei* is the best of all passion fruits, being as large as a duck's egg and of an orange-yellow colour; this species was originally brought to Madeira—probably in transit—from the Canaries, but was unknown a few years ago in any of the islands beyond these. The entrancing beauty of the flower alone would entitle the plant to a conspicuous place in any garden, but the fruit is in request beyond these limits and is hence exported in increasing quantities. I have sent the seed to almost all our dependencies, and have excellent reports of its establishment and appreciated value.

Cucurbitaceæ.

The cucumber, *Cucumis sativus*, uncommon in the Canary and Cape Verde Islands, abounds in Madeira, where a stunted-looking variety grown on the hot rocks in a few inches of soil acquires an excellence of taste and quality hard to equal elsewhere. A cucumber or two, with a little salt and a loaf of bread, makes a satisfying breakfast for many a labourer. Of the gourds, *Cucurbita melanosperma* is a watery constituent of an agreeable Portuguese soup, and is supplied in bulk as a table vegetable to passing ships. This gourd is well known in the Canaries, but no further south. *Cucurbita moschata* is largely cultivated in all the islands, though attaining in no other place the excellence it possesses in Madeira, where for at least six months in the year it provides perhaps one-third of the daily nourishment of the people. The importance of this esculent in the Atlantic islands can hardly be overrated, and its value is quite comparable to the importance of the potato in Ireland; with its large supply of saccharine and farinaceous material and its facility of combination by boiling with fatty substances it makes a most nutritious food, as is shown by the surprising muscular power and endurance of the Portuguese peasantry, who so greatly depend on it. I have sent seeds of this truly desirable food far and wide.

Sechium edule chocho, the pepinella, seems to have come to Madeira about 100 years ago A full description of the species and its attributes would occupy the entire time allotted to this lecture. Besides the charm of its cultivation, its surprising growth, and the peach-like fragrance of its creamy flowers, the plant yields now a copious and unfailing supply of an esculent of the first order in food value. I have sent this wonderful vegetable to many countries—selecting the green and more tasty variety, though Sir Daniel Morris tells me that the white sorts do better in the tropics, and it is now established in many regions formerly devoid of cucurbitaceous produce. The sechium is propagated by planting the one-seeded fruit entire, the whole gourd enlarging into a persistent subperennial rhizome a foot or more in diameter and sending up annually, when well-established, 100 or more shoots to cover a trellis of enormous extent from whence hangs the small fruit in myriads. I know of no other such transmutation of the nutrient surrounding matter of a seed into the permanent tissue growth of the new plant. The pepinella is boiled as a favourite vegetable in the winter months and has an agreeable nutty flavour, together with a greater power of combining with fats than I have observed in any other gourds. It is, moreover, free from fibre and very digestible; I have employed it to great advantage boiled with cream and other fats as a non-irritant food in gastric ulceration, enteric fever, and other intestinal disorders.

Coffee.—Rubiaceæ coffea arabica, the Madeira coffee tree, once cultivated with great success with respect to the excellence of produce, was entirely destroyed before we learned how to restrain the depredations of the Argentine ant; it is now slowly re-appearing. The plant grows freely in the Western Islands, and the principal valleys of the Portuguese Cape Verde Islands are jungles or thickets of coffee growth yielding in great abundance a small berry of excellent quality. Apart from the Liberian species, with which I have not succeeded in Madeira, several new varieties of this important esculent have recently been found in the development of our Central African dependencies. One of these—*Coffea robusta*—is being distributed from Northern Nigeria and yields a fairly large berry of excellent flavour; the leader of the present Grabham Mission to Lake Tsana in Abyssinia (whence the coffee tree is believed to have first nor can we agree with certain premises used in their explanation. Cammidge and his collaborators found: (1) That the effect of a purely protein meal in raising the blood-sugar was little if any less than that of carbohydrate foods; (2) that, in the normal person, a fall in the blood-sugar level occurs during the first half hour after a mixed meal, this fall coinciding with the "alkaline tide" in the urine and the passage of sodium-ions from the stomach into the circulation; (3) that the normal blood-sugar curve after a mixed meal containing carbohydrate included this preliminary fall in the first half hour, then a rise, reaching its maximum in three hours after the meal, followed by a gradual fall until the blood-sugar reached its original level at the fifth or sixth hour. In contrast with these, our results in similar experiments, while confirming those of Jacobsen,[5] Maclean and de Wesselow,[3] Frank and Melhorn,[6] and others, show: (1) That for at least five hours after the ingestion of protein there is no appreciable rise in the blood-sugar; (2) that in a normal person the effect of a mixed meal containing carbohydrate is to produce an immediate rise in the blood-sugar without any preliminary fall; (3) that, after such a meal, this rise is greatest during the first half hour or so and reaches its maximum within 60 minutes, subsiding quickly to regain its original level within two hours. Moreover, their explanation of the factors which promote glycogenolysis through activation of the diastatic ferment of the liver does not take into account that the liver is not richer in diastase than the muscles, lungs, kidneys, and other organs; that it is extremely improbable that the absorption of acid is so great as to overcome the regulating mechanism in the blood, and so produce an actual increase in H-ion concentration; and that, given the presence of a certain minimum of salts for diastatic action, a mere excess of sodium chloride in the liver cells will not increase that action in proportion to the excess. Prior to Cammidge, Forsyth, and Howard, similar ideas were expressed by Langfeldt.[8]

Experiment on Rôle of Acid Secretion in Rise of Blood-Sugar.

The following experiment which we carried out affords more practical evidence that the acid secretions during digestive activity in the stomach play no part in influencing the rise in blood-sugar following the ingestion of food. To a healthy adult 50 g. of glucose dissolved in water were given by the mouth. The blood-sugar rise was determined by estimations of blood taken at intervals of 20, 30, 40, 60, and 100 minutes after. A week later, under similar conditions, an Einhorn's tube was passed into the jejunum (position confirmed by X ray), 50 g. of glucose were then passed into the jejunum and the blood-sugar rise determined at similar intervals. The results were as follow:—

(1) 50 g. glucose absorbed by stomach; (2) by jejunum.

	(1)	(2)
	Blood-sugar per cent.	
20 minutes	0·151	0·136
30 ,, ...	0·153	0·167
40 ,, ...	0·161	0·161
60 ,, ...	0·132	0·117
100 ,, ...	0·102	0·102

These results show the close similarity of the blood-sugar rise which occurs whether the material is first taken into the stomach or passed directly into the small intestine. In the latter case it is difficult to conceive that the result could be influenced in any way by the production of acid in the stomach. Moreover, experiment shows that strongly acid or alkaline solutions of sugar taken by mouth produce the same change in blood-sugar concentration.

Details of Method for Determining Liver Efficiency.

The patient must fast for at least three hours before the test is carried out. In the normal person the influence of the preceding meal on the blood-sugar will have passed off. *It is perhaps better in many cases* to make the interval longer than three hours, and in hospital practice our routine is to instruct the patient to eat a very light breakfast and then attend at the laboratory four or five hours later. The first sample of blood for sugar estimation is taken immediately before the patient drinks the lævulose, further samples being taken at half-hourly intervals for two hours. With a suitable method, estimations of the blood-sugar in these samples can be carried out in the intervals between the taking of the blood. The lævulose is given dissolved in 100 to 200 c.cm. of water. The amount varies with the size and weight of the patient. The following are convenient amounts:—

For a person of		lævulose.
80 kilos	50 g.	
60 ,, ...	40 ,,	
40 ,, ...	30 ,,	

In normal persons these amounts of lævulose will cause no appreciable rise in blood-sugar. But for the purpose of the test they should not be exceeded. In many normal individuals whose blood-sugars show no rise after 50 g. lævulose, a definite rise can be provoked with 100 g., which appears to be beyond the immediate capacity of even a healthy liver. It is for this reason that restriction of the amounts must be made.

For clinical purposes a micro-chemical method of blood-sugar estimation is necessary. Venous puncture is thereby obviated. We have used Maclean's[7] method throughout. In this, capillary blood is taken from a needle prick into a 0·20 c.cm. pipette, with little or no discomfort to the patient. In a series of cases we carried out urinary examinations to determine the degree of glycosuria which resulted. Urine was collected at the same half-hourly intervals at which the blood was taken. For qualitative purposes Fehling's test and Seliwanoff's resorcin test for lævulose were used. Quantitative estimation of urinary sugar was carried out by means of Bertrand's method and the Safranin method.

The Response in the Normal Individual.

In Table I. the result of the test in five apparently healthy cases is given (one, D. J., was a laboratory assistant, the others out-patients of the hospital class). It will be seen how slight an effect doses of 30 to 50 g. of lævulose have on the blood-sugar. In no case was there a definite rise of even 0·02 per cent. The greatest rise was only 12 mg. per 100 c.cm., and this was in the case (M. R.) of a pale anæmic woman in whom syphilis had been suspected and who, therefore, might justifiably have been excluded from the series. We have taken the mean of these curves and plotted them graphically in Fig. 1. This will be taken as the normal expression of the liver function test in the healthy individual, and used as a basis of comparison for the results found in the other cases we have investigated. In one of these cases (H. W.) a comparison of the lævulose and glucose blood-sugar curves was made; 30 g. of glucose were given by the mouth; the initial blood-sugar level was 0·086 per cent., and at half-hourly intervals after the glucose the successive levels were 0·168 per cent., 0·109 per cent., 0·092 per cent. A rise of 82 mg. per 100 c.cm. which, it will be remembered, is a normal result with glucose.

TABLE I.—*Results of Liver Efficiency Test in the Normal Individual.*

—	Age.	Weight in kilogrammes	Amount of lævulose given in grammes	Blood-sugar per cent.			
				Before taking lævulose.	½ hour after.	1 hour after.	1½ hours after.
D. J. . .	24	70	50	0·090	0·089	0·099	0·090
H. W.	33	64	30	0·082	0·091	0·084	0·083
M. R. . .	26	55	30	0·086	0·098	0·095	0·091
F. F. . .	37	—	50	0·102	0·104	0·101	0·100
W. R.	55	—	50	0·102	0·102	0·112	0·109

We have stated that even in the normal individual a definite rise in blood-sugar will follow the ingestion of lævulose if a large enough amount be taken. In *cases we have investigated, 100 g. of lævulose have* provoked such a rise, when 50 g. had no effect on the blood-sugar. A typical example gave the following dozen 40 lb. From Madeira the onion is chiefly exported to Brazil. As an essential in our food and as a condiment, I need say nothing except to point out the delicacy of flavour in these subtropical forms, and the superiority of southern methods of serving. Long before the physiologists began to speak about vitamins the general public had shown an instinctive greediness for the onion which, though poor in caloric value, abounds in accessory food value. Before the war in 1914, imported onions, mainly from Spain, Portugal, and the Atlantic islands into this country, were valued at over one million sterling—a sound investment, providing a distinct mitigation to the people of this country of the poverty of their winter diet. Nelson, 130 years ago, had also learnt the value of the onion at Naples, and I heard in early life from the daughter of the Captain Codrington who fought under him at Trafalgar, that every ship in a blockading squadron had to be copiously supplied with this valuable antiscorbutic.

Sugar.

The sugar cane, *Saccharum officinarum*, is a general object of cultivation in all the islands, and in Madeira covers every available space with a sunny exposure from the sea-level to 1000 ft. above. The juice is devoted partly to the distillation of alcohol, but mainly to the manufacture of excellent sugar. The presence of the sugar cane in Madeira, occupying ground which could be devoted more profitably to the production of the custard apple and a variety of fruits and vegetables which Madeira only can supply in their first freshness to the London markets, is a reproach to the fiscal administration of the Government of Portugal.

Fungi.

All the well-known fungi of the British islands are well represented in the super-equatorial regions of the East Atlantic. Some are very poisonous, and these so nearly approach the edible varieties in appearance that, notwithstanding the admirable coloured charts now published, I have confined my commendation of them to two unmistakable forms—viz., our common agaricus and the *Boletus edulis* which abounds in the pine woods of Madeira in the autumn months. The boletus is a substantial esculent having a tangible protein value, and when properly prepared forms a valuable and agreeable contribution to our dietetics, though Ambroise Paré contemptuously dismisses the entire order as "an excrescence of the earth's superfluity not void of a venomous quality."

Absence of Deficiency Diseases in the East Atlantic.

It will be readily understood in the sketch I have now given of the wealth and variety of our vegetable food-supplies, perennially fresh and plentiful, that the native races in these regions do not suffer from the so-called deficiency diseases associated with the absence of vitamin substances. Open-air life and freedom from excessive changes of temperature must also contribute to this immunity. In the great war we, at Madeira, were taken by surprise; to a great extent we exhausted our local resources before we realised that normal importations of wheat and maize would completely cease. In those days we were insufficiently fed; we lost weight, and you could see among the people the vacancy of expression, apathy, and depression so well known in association with incipient starvation, and it was then that I reaped the full benefit of the botanical knowledge—built on the meagre foundation laid in the remote times of my early medical curriculum—which I have since acquired and which has enabled me as a referee in these regions to minister to the constant requirements of new provinces of the Empire.

Botanical Education.

I remember the dismay at the British Association for the Advancement of Science with which the announcement that botany would probably have to disappear from the overladen curriculum of essential requirements of medical education was received, and the strongly expressed opinions that a place should be allotted to some instruction at least in this science, however elementary. About that time Sir George Nares, whose crews had suffered terribly from scurvy in his then recent Polar expedition, and in whose ships the superior antiscorbutic value of lemon juice over lime juice had been demonstrated, called to confer with me, on his way to Patagonia, as to the material which might be available in Madeira to ferment into the sort of beer which our splendid navigator, Captain Cook, found effective in those days of miserable equipment 140 years before. Cook, doubtless under the guidance of Banks and Solander, seems to have fermented just anything, and the resulting nauseous liquid amply confirms the scathing criticism of Burton on the beer in vogue 100 years before Cook's time: "*Nil spissius illa dum bibitur, nil clarius est dum mingitur, unde constat quod multas fœces in corpore linquat.*"

Nares, with my help, concocted something at least less nauseous, and I also supplied him with a quantity of sprouting sweet potatoes which, kept moist with a fertilising fluid, gave a copious yield of green shoots and for many weeks were very serviceable; further, I gave him that information respecting tomatoes and onions, already spoken of, while we sat under the shadow of a gigantic tulip tree which Cook and Solander had planted on one of my terraces 120 years before. We spoke much that evening—probably after dinner—of the customary excesses of our diet beyond the requirements of energy and repair, and of the waste of effort exerted in eliminating at least half of the protein taken in excess of bodily needs; true physiological economy is the judicious application of scientific truth to the art of living.

ANIMAL FOODS.

The animal foods of the Atlantic islands I can pass over with the general remark that cattle of every well-known breed abound in proportion to their means of sustenance, and that we have at all seasons poultry, eggs, milk, and butter in abundance, both for local use and exportation. Several breeds of goats are met with in all our mountains; some have run wild and subsist in plenty in inaccessible places. We rely, too, on our goats' milk, which is excellent and happily free from the infection which Sir David and Lady Bruce investigated at Malta.

SEA FOODS.

I will now mention very briefly the salient points relating to the latent, almost unexplored sources of food which the surface water and abysmal depths of the seas in these regions invite us to explore. The surface plankton, or floating life, and the condition of the sea bottom with its deposits and deep-sea organisms, present general problems full of economic, biological, and geological interest. I can only hope to illustrate by a few examples the scientific importance and practical utility attaching to the study of these surface and abysmal conditions.

Tunny.—From the economic point of view the thynnus or tunny is our most important fish. Known everywhere, it is never long absent from our island markets, and scattered examples of enormous size appear throughout the year; this fish is gregarious in habit, visiting Madeira in vast numbers in the early spring, driving inshore frightened shoals of its own and other smaller species. In Atlantic regions it is captured with a stout hook baited with a living mackerel or herring, and a full-grown example 10 ft. long generally weighs about 400 lb., reaching in occasional instances the extreme weight of twice this ponderous bulk. The life-history of the tunny is imperfectly known; the rate of growth to maturity, the locality it haunts, and its means of sustenance in early life all need investigation, but its esculent value may be gathered from the fact that when eviscerated and prepared for market quite 85 per cent. of the substantial fish-meat is available for human food. A certain amount of tunny flesh is now canned and exported, but further investigation and improved methods of fishing will presently show what huge reserves of this valuable food at present escape us. The tiny scales entirely surrounding the body give the skin a smooth appearance, and excellent leather is now being manufactured from this and other sea monsters.

The flesh of the tunny fish, like that of many other Scombridæ, seems to carry with it a liability to a mild and evanescent form of urticaria. I was once present at a dinner where 7 out of 12 guests were victims of some noxious substance thus conveyed in eating. The chef had served up an appetising course of "veal" cutlets made of the pallid portion of tunny with a taste suggestive of anything but fish, and two hours later the recipients were comparing notes of their symptoms and highly-coloured countenances. I advised the hostess on future occasions to have her "veal" served up with fennel sauce, which by some beneficent instinct people have learned to eat with mackerel and the like, thereby gaining immunity from nettle-rash. Funchal,

D. In Table II. results of the test in slight cases of salvarsan jaundice are given. In these patients the test was applied in the stage of recovery, when jaundice was the only remaining symptom. In each case there was a definite abnormal rise, greater than could be accounted for by experimental error, which we look upon as evidence of varying slight degrees of liver inefficiency. Generally speaking the evidence suggests that the height and length of the blood-sugar curve are in proportion to the degree of liver damage present. In this group the case which showed the greatest rise (E. H.) was more affected than any of the others; while the case (M. W.) with the least rise had practically recovered from the illness, a slight tinge of jaundice in the conjunctivæ being the only remaining sign of disease.

TABLE II.—*Results of Test Showing Slight Degrees of Liver Inefficiency.*

—	Age.	Amount of lævulose given in grammes.	Blood-sugar per cent.			
			Before taking lævulose.	½ hour after.	1 hour after.	1½ hours. after.
A. W. ..	38	50	0·094	0·117	0·120	0·108
E. H. ..	26	30	0·125	0·151	0·148	0·128
M. W. ..	21	30	0·093	0·098	0·107	0·104
R. W. .	29	50	0·109	0·109	0·134	0·118

Result of the Test in Control Cases.

In order to control these results in normal individuals and in cases of toxic jaundice, we applied the test to various patients from a medical ward. In Table III. the results of the test in eight different cases are given. They afford evidence of the value that the test may have in determining the efficiency of the liver. We used, as standards of comparison, the results obtained in the study of normal individuals and of cases of toxic jaundice, whereby they are classified as (1) normal, (2) slight liver inefficiency, (3) moderate liver inefficiency, (4) severe liver inefficiency, (5) extreme liver inefficiency.

TABLE III.—*Results of Test in Control Cases.*

—	Age.	Disease.	Amount of lævulosegiven in grammes	Blood-sugar per cent. before and at half-hour intervals after lævulose.				Result.
1	37	Lymph.	50	0·098	0·104	0·101	0·100	N.
2	17	Ac. neph.	30	0·102	0·104	0·104	0·100	N.
3	—	Med. tum.	30	0·091	0·100	0·102	0·090	N.

6	54	Tab. dor.	50	0·082	0·118	0·125	0·114	S.L.I.
7	70	Malig. liver.	40	0·106	0·134	0·138	0·134	M.L.I.
8	9	Cat. jaun.	25	0·120	0·164	0·176	0·151	Sev.L.I.

Disease.—Lymph., lymphadenoma. Ac. neph., acute nephritis. Med. tum., mediastinal tumour. Tab. dor., tabes dorsalis. Ob. jaun., obstructive jaundice. Cat. jaun., catarrhal jaundice.

Result.—N., normal. S.L.I., slight liver inefficiency. M.L.I., moderate liver inefficiency. Sev.L.I., severe liver inefficiency.

Normal results were found in four cases—viz., lymphadenoma, acute nephritis, mediastinal tumour, and a tabes dorsalis which had been treated with salvarsan without ill-effects up to within two weeks of the time of examination. In none of these cases was there an appreciable rise in blood-sugar after the ingestion of lævulose. *Slight degrees* of liver inefficiency were found in two cases: (1) A case of obstructive jaundice, which subsequent operation proved to be due to a gall-stone in the common duct; and (2) a case of tabes dorsalis treated with salvarsan up to within three weeks of the time of examination without apparent ill-effects. In these cases lævulose produced blood-sugar rises to 0·125 per cent. and 0·133 per cent., reaching their maximal height in an hour. A *moderate degree* of liver inefficiency was found in one case. This was a case of malignant liver in a man of 70. Here there was a blood-sugar rise to 0·138 per cent. after an hour, which was still up to 0·134 per cent. after an hour and a half. A *severe degree* of liver inefficiency was found in one case. This was a case of catarrhal jaundice in a girl of 9 years. In this there was a rise of 56 mg., reading to 0·176 per cent. after an hour, and to 0·151 per cent. after an hour and a half. This result is of some significance. The girl was not so deeply jaundiced as the man with obstructive jaundice from gall-stone, nor did her urine contain as much bile pigment; yet the test revealed a much greater degree of impairment of liver function. This would suggest that there was much more parenchymatous involvement in the case of catarrhal jaundice than in the case of obstructive jaundice with gall-stone in the common duct.

These results show that the test revealed some diminution in the functional capacity of the liver in four cases, in three of which some damage of the liver could be presumed to be present on clinical evidence. The fourth case had been treated with silver-salvarsan (4·65 g.) up to three weeks before the test was carried out. It is reasonable to assume that the test revealed some latent liver damage which was not apparent on clinical evidence. In four cases the test showed normal liver efficiency to be present. In none of these cases was there clinical evidence of liver disease.

A blood-sugar rise after lævulose would, of course, be obtained in patients suffering from diabetes, but in such cases the history and clinical symptoms should indicate the probable nature of the condition.

The Kidney Threshold for Lævulose.

In certain of the patients investigated we compared the results obtained by estimation of changes in blood-sugar concentration as described above with the results given by the Strauss test for hepatic insufficiency. In the Strauss test[10] lævulose is given by the mouth and the urine is collected for examination at hourly intervals afterwards. If sugar appears in the urine after the ingestion of 100 g. of lævulose it is taken as evidence of decreased liver efficiency. The results of the test appear to be very indefinite. Churchman[11] used it in the Johns Hopkins Hospital and discarded it, coming to the conclusion that it gave no conclusive evidence of the condition of the liver. In our own investigations Strauss's test has given very inconsistent results. Using 50 g. of lævulose, sugar appeared in the urine of some of the normal cases, and did not appear in some of the cases with liver disease. This inconsistency is explained by the fact that the appearance of lævulose in the urine depends more on the "kidney threshold" for lævulose than on the liver's efficiency in storing the sugar. The kidney threshold for lævulose appears to be much lower than the threshold for glucose, and actually varies greatly in different individuals. Graham[12] noted in a case he investigated that the threshold for lævulose was below 0·150 per cent. and for glucose above 0·195 per cent. In six of our cases we found that lævulose (sufficient to reduce Fehling's solution) was excreted in the urine by the time the blood-sugar had reached the following levels:—

	Blood-sugar per cent.
(1) Age 8 years	0·097
(2) „ 57 „	0·131
(3) „ 70 „	0·130
(4) „ 46 „	0·110
(5) „ 23 „	0·126
(6) „ 53 „	0·133

One case with no apparent disease of the liver gave a normal reaction to the liver function test, yet lævulose appeared in the urine. Using 30 g. of lævulose the blood-sugar levels were: before 0·084 per cent., half an hour after 0·093 per cent., one hour after 0·095 per cent., one and a half hours after 0·084 per cent. A specimen of urine collected one hour after ingestion of the lævulose contained sugar. It reduced Fehling's solution and gave Seliwanoff's test for lævulose. In view of the very slight rise in blood-sugar the presence of lævulose in the urine of this patient is remarkable, but it appears to indicate that in certain subjects a cable which revealed the occurrence of a volcanic outbreak in this oceanic depth, and showed what may often happen on the ocean floor with little or no evidence at the surface. The cable itself beneath was destroyed for several miles, and the extent of the disturbance was only revealed when, in laying the cable afresh, it was found necessary to travel 15 miles away before a smooth bed could be found beyond the jagged rocks into which the placid ocean bed had been torn.

CONCLUSION.

I confess to a sense of disappointment in view of the status and repute of this College, and of the pride every Fellow feels in our traditions and equipment, that the coöperation sought by the Government of this country during the recent war as to food, dietetics, hygiene, and cognate matters was not required of us in corporate capacity. The work I am indicating was truly accomplished in association with us; neither could the Royal Society have furnished the advice and information needed by the Government and nation in such matters without the able and disinterested coöperation of our distinguished colleagues. We are largely engaged in meeting the provision of our country's need of competent medical practitioners. We are an examining and licensing body truly, but much more. We are the custodians and exponents of science far beyond the narrow definition of medicine itself, and it will be found that in any committee appointed to report on a matter of collateral science—and what science is not collateral to ours?—the effective output has been largely and perhaps mainly due to some guiding influence issuing from within these walls.

THE USE OF LÆVULOSE AS A TEST FOR HEPATIC INEFFICIENCY.*

BY J. C. SPENCE, M.C., M.D. DURH.,
M.R.C.P. LOND.,
JOHN AND TEMPLE RESEARCH FELLOW;
AND
P. C. BRETT, M.B., B.S. LOND.
(From the Medical Unit St. Thomas's Hospital.)

LÆVULOSE as a test for liver function has been extensively used in the past by Strauss and various others, but for reasons which will be fully described later the results obtained were unreliable. All the observers based their conclusions on the absence or presence of glycosuria after the patient had received a large dose of lævulose by the mouth. Recent observations on the increase in blood-sugar concentration, brought about by the ingestion of carbohydrate, point to the conclusion that the degree of hyperglycæmia produced is more important than the presence or absence of glycosuria in indicating liver inefficiency. Hopkins,[1] Hammam,[2] Maclean and de Wesselow[3] and others have shown that if 50 g. of glucose be given to a normal adult individual after he has fasted for three or four hours an immediate rise in the sugar content of the blood can be demonstrated. If blood-sugar estimations be made immediately before and at half hourly intervals after the ingestion of the glucose, it will be found that this rise is from an original basal level near 0·100 per cent. to about 0·170 to 0·180 per cent. at the end of the first half hour. At this point a rapid subsidence takes place, and the sugar content of the blood falls to or below the original level within an hour or an hour and a half. When plotted graphically the result represents the normal "blood-sugar curve" for 50 g. of glucose. Alterations in sugar tolerance will affect the shape of this blood-sugar curve. In conditions of decreased sugar tolerance the rise is abnormally high and prolonged. If the blood-sugar has not returned to its original level within one and a half or two hours, a diminution in the sugar tolerance is considered to be present. All the available evidence suggests that the nature of this curve is chiefly dependent on the power of the liver to store sugar in the form of glycogen. Maclean and de Wesselow[3] pointed out that the only sugar in ordinary use which did not produce a rise in blood-sugar concentration was lævulose. They showed that in the normal healthy adult 50 g. of lævulose could be taken without producing any appreciable increase in the blood-sugar; this observation they made use of in testing for liver efficiency in various cases, on the supposition that a defective liver mechanism would result in the production of lævulose hyperglycæmia.

That lævulose in the amounts used by Maclean and de Wesselow produces no definite increase of blood-sugar we have confirmed. In some cases a very slight rise of from 5 to 10 mgm. per 100 c.cm. was observed, a rise almost within the bounds of experimental error. The normal blood-sugar curve after 50 g. of lævulose can thus be represented by a continuous straight line from the original blood-sugar level, or a line showing slight oscillatory deviations of 5 to 10 mgm. per 100 c.cm. from the original level. A definite rise in the blood-sugar of even 20 mgm. per 100 c.cm. after 50 g. lævulose indicates a diminution of sugar tolerance.

Liver Function and Lævulose and Glucose.

The only explanation of the difference in the blood-sugar curves following the ingestion of these two sugars that can be put forward in the present state of our knowledge is, that in the case of lævulose, the sugar, after absorption from the alimentary tract, is so readily taken up by the liver and stored as glycogen that it does not appear in the systemic circulation. If the functional capacity of the liver be diminished in any way—e.g., in the degeneration of hepatic parenchyma seen in salvarsan poisoning—it will not be able to deal with the 50 g. of lævulose presented to it. The lævulose will then pass to the systemic circulation, where a rise in the blood-sugar content will result. The greater the degree of liver damage the more lævulose will pass through, and the greater will be the rise in the blood-sugar curve.

Glucose is not assimilated and stored as rapidly as lævulose. Even in the healthy individual it passes readily through the liver to circulate for half an hour or more in the systemic circulation, producing there, as we have seen, a definite rise in the blood-sugar. It appears to be abstracted from the blood stream by the intervention of a carbohydrate storage mechanism, which does not, however, come into play effectively until half an hour or more after the ingestion of the sugar. In the presence of an inefficient liver this abstraction and storage of the glucose is delayed. A high and prolonged blood-sugar curve results. But the variation from the normal is not so marked as it is in the case of the altered lævulose curve of liver inefficiency.

A Theory Tracing Rise of Blood-Sugar to Absorption of Salts.

We are aware that Cammidge, Forsyth and Howard[4] have recently advanced a theory which opposes this explanation. They argue that the rise of the blood-sugar following the ingestion of food results from changes in the reaction of the blood produced by absorption of salts formed from the digestive secretions; and that the rise results from the breaking down of preformed glycogen—an increased glycogenolysis—in the liver. Their theory explains this increase in glycogenolysis as being caused by the active stimulation of the diastatic ferment of the liver, which in its turn is brought about by three factors: an actual change in the hydrogen-ion concentration of the blood, an increased permeability of the liver cells to sodium chloride, and a release of the inhibitory action of the pancreas. Their argument is based, however, on experimental work in which certain results were quite different from the results which we, and many other workers, have reached in covering the same ground;

The expenses of this investigation have been borne by the al Research Council.

of the tuberculin. From a theoretical point of view our supposition seemed to be supported by an investigation of Ricker and Goerdeler,[3] who had shown that in rabbits a sensitiveness of the blood-vessels of the omentum to various drugs was greatly increased by experimentally induced local tuberculosis.

These considerations led us to apply the v. Pirquet test to some asthma patients, and we were highly impressed by the very strong reactions given in these cases. Since at that time the results of our treatment of bronchial asthma were, as stated above, not satisfactory, we determined to investigate whether an improvement in asthma cases could be obtained with tuberculin treatment. The results in our first cases were so encouraging that we deemed it necessary to study the matter on a larger scale. We are now in a position to report on 28 cases of bronchial asthma and two cases of hay fever, treated with tuberculin injections.

Number of Patients Showing Positive v. Pirquet Test.

Of 34 cases of bronchial asthma which have come under our care since we started tuberculin treatment, 30 gave a positive v. Pirquet test and four patients were negative. The four negative cases were not treated with tuberculin and will not be considered further in this paper. We had only four cases of hay fever during this period, all of them women—three Dutch and one Hungarian. Two of them had a very strong positive reaction, one a moderate reaction (she refused to be treated with injections), and one (the Hungarian) had a negative reaction and was treated with pollen. So there remained only two cases of hay fever for tuberculin treatment.

Dosage of Tuberculin.

The tuberculin used was Koch's T.O.A. All injections were given subcutaneously. The body temperature of the patient was carefully controlled during the whole course of the treatment. We always began with low doses of tuberculin—mostly 1 c.cm. of a 1 : 100,000 dilution—which gave no general reaction. In our first cases we increased the dose of tuberculin with each injection (providing that the former injection had not produced a temperature reaction) attempting to administer high doses in a relatively short time. During the treatment of these cases, however, we got the decided impression that the latter procedure was wrong, and that it was better to keep to very low doses; this we did in all the later cases. This point will be referred to again.

Additional Measurements.

Although we are quite certain that the tuberculin treatment forms the most important part of our therapy, we took the precaution of making all other conditions as favourable as possible. This was especially necessary, since we wanted a cure to be as short as possible. Moreover, additional measures were indispensable during the first days of the treatment, when the effect of the tuberculin treatment was not yet manifest. The first step was to keep the patient in bed till his asthma was cured. Sometimes external circumstances prevented this, and the patients had then to be given ambulant treatment. We gave a protein-free diet and inhalations of benzylbenzoate, as mentioned above. Those patients who suffered from chronic bronchitis were given codeine and potassium iodide. After entering hospital, the patients were not allowed to take any patent medicine or to smoke asthma cigarettes; during the first days acute attacks of asthma were immediately cut short with an injection of adrenalin; and we consider it important not to allow the patient to have a single attack of asthma from the moment he enters our care. As a rule these adrenalin injections had only to be given during the first days; many patients received only three or four of them and some only during the first day.

Duration of Cure.

Nearly all the patients suffered from acute attacks of asthma on entering into our care. These attacks generally disappeared for good after the first two or three tuberculin injections; sometimes they did not reappear after the first injection. As a rule, patients were kept in bed till three days had elapsed since the last attack. During the next six days they were gradually allowed to get up and go out; the majority were able to leave the hospital 10–14 days after entrance. As we did not know how long the effect of the tuberculin would last, we continued our tuberculin injections for two or three months, during the first weeks giving an injection once a week, and afterwards once a fortnight. In many cases—especially those of long-standing asthma—a chronic bronchitis was present, which had to be treated after the acute attacks of asthma had subsided. This treatment, of course, took a longer time, and autogenous sputum vaccines were sometimes required. Apart from this complicating bronchitis, it can be stated that as a rule the acute attacks of asthma vanished within a few days of the beginning of tuberculin treatment.

Results of Treatment.

Before entering on a discussion of the results, very brief extracts of the clinical histories of 12 patients treated with tuberculin are given.

(1) E., schoolboy, aged 17. Asthmatic attacks from earliest years; tried all sorts of treatment; many recent attacks. Protein sensitisation tests negative; v. Pirquet + +. Tuberculin treatment (ambulatory) started 9/11/21. Tuberculin 1 : 100,000–1 : 10,000; purine-free diet (P.D.); benzyl benzoate (B.B.). Result: Completely cured after some weeks.

(2) K., kinema attendant, aged 25. Acute attacks of asthma from 8 years old. Very heavy attacks, with extreme dyspnœa and often fever, keep him in bed for weeks. Skin reaction: crab +; swine serum +; v. Pirquet + + +. As crab treatment-set was not obtainable, treated with swine serum in increasing doses; reacts very strongly. Result: No improvement; 7/7/20, tuberculin treatment started. 1 c.cm. 1 : 100,000–5 : 10,000, ambulatory treatment. (B.B. and P.D.) On 16/9/20, dose of tuberculin increased from 1 : 10,000 to 2 : 10,000; that night a severe attack of asthma. After that the tuberculin dose was lowered and very gradually increased again. Patient remains free from attacks; then, however, he interrupts treatment and eats meat; *11/5/21 contracts a cold, heavy attack of* asthma; again P.D. and tuberculin. Since then no further attack.

(3) N., chauffeur, aged 30. Heavy attacks of asthma *since age of 20, becoming worse latterly; last seven years* absolutely continuous dyspnœa, very marked bronchitis; patient slept very badly and had to give up profession; v. Pirquet + + +. 18/3/21, taken into hospital and tuberculin treatment started: 1 c.cm. T.O.A., 1 : 100,000; doses gradually increased to 8 : 100,000. During first three days adrenalin injection two or three times a day, then stopped; 3/4/21, tuberculin dose increased to 1 c.cm. 1 : 10,000; patients gets attack of asthma, which is cut short with adrenalin; 20/4/21, tuberculin 1 c.cm., 1 : 1000; temperature rises to 38°C. during two days. Patient very ill and many attacks of asthma. 23/4/21, no attack of asthma, tuberculin injections down to 1 : 100,000; 4/5/21, sent home with chronic bronchitis but free from attacks; 6/5/21, back in hospital with violent attack contracted immediately after coming home. In hospital, tuberculin treatment, 8/6/21. Sent to brother in another town. Completely well, takes up profession again, rides in car whole day. 8/7/21, returns to his own home for one night and gets an attack. Advised to move to other house; remains free from attacks for two months, but visits his home against our advice four or five times and gets attacks there every time. The last attack does not disappear on leaving his home. Has to be taken into hospital again.

(4) G., physician, aged 38. Heavy attacks of asthma since age of 16, latterly every night. Had to give up general practice, only does hospital work. V. Pirquet + + +. Taken into hospital and tuberculin treatment started. 2/5/21, 1 c.cm. 1 : 100,000. First night no attack and since that time attacks have not returned. Is able to walk 20 kilom. without becoming dyspnœic.

(5) H., colonial official, aged 48. Asthma since age of 30. Of late years about five attacks a day; has to smoke asthma cigarettes constantly to reduce them; v. Pirquet +; chronic bronchitis, emphysema; 20/5/21, taken to hospital, tuberculin treatment started. First day three injections of adrenalin, second and third day two injections. Since 30/5/21 no adrenalin injections necessary. Leaves hospital after 13 days with chronic bronchitis, but absolutely free from dyspnœa. 14/6/21, eats large amount of beef-steak, gets asthma attack, which lasts two days. Since then keeps to P.D., and is free from attacks.

result: before the 100 g. of lævulose 0·089 per cent., half an hour after = 0·117 per cent., one hour after = 0·153 per cent., one and a half hours after = 0·118 per cent.

The Result of the Test in Toxic Salvarsan Jaundice.

The condition of toxic jaundice which occurs not infrequently, after the administration of salvarsan, has provided clinical material for the application of the test. Turnbull's[9] very careful histological examinations in fatal cases showed how the liver in particular is affected in this condition. In all cases he found the liver lesion to be more severe than that in any other organ. This is an important point to establish, for thereby we can exclude the possibility of the results we have obtained in the following curves being due to pathological changes in the intestine, pancreas, endocrine glands, and other organs.

We have had an opportunity of applying the test to cases of toxic salvarsan jaundice of varying degrees of intensity. One of these was ultimately fatal, and post-mortem confirmation of the liver damage was obtained. A few were extremely severe with slow recovery; others were moderately or very slightly affected. In every subject the test revealed an impairment of the functional capacity of the liver; but, as might be expected, the most striking result was in the fatal case. In this patient the symptoms and clinical signs were not more marked than in other moderately affected cases who recovered quickly, but the test showed that there was a higher degree of liver damage than was indicated by the clinical picture. The result of the test was confirmed by the subsequent course of events, for the man died a few days later.

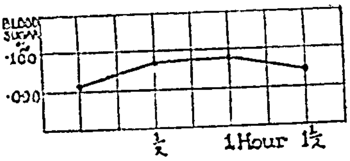

FIG. 1.—Normal blood-sugar curve after 30 to 50 g. of lævulose (see Table I.). This result denotes normal liver efficiency.

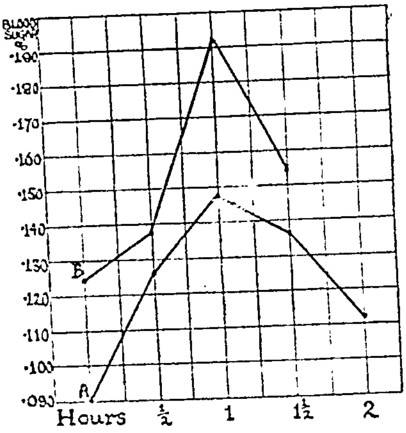

FIG. 2.—Results of lævulose tests in two cases of salvarsan jaundice, showing (A) moderate degree and (B) severe degree of liver inefficiency.

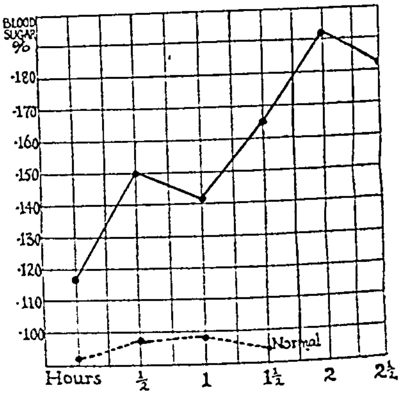

FIG. 3.—Result of lævulose test in a fatal case of salvarsan jaundice with extreme degree of liver inefficiency (see text). Note the high and prolonged rise in blood-sugar compared with the result in a normal individual.

A. The following is an example of a *moderate* degree of liver inefficiency as revealed by the test.

W. C., aged 23, a moderately severe case of toxic salvarsan jaundice with symptoms of anorexia, vomiting, and jaundice appearing after two courses of ten N.A.B. injections and five silver-salvarsan injections. The liver-function test was carried out after the jaundice had existed for four weeks. There was no vomiting at this time, the patient feeling fairly well, but a deep tinge of jaundice persisted. 50 g. of lævulose were given. The levels of the blood-sugar curve (Fig. 2) were:—

		Blood-sugar per cent.
(1) Before	50 g. lævulose	0·090
(2) ½ hour after		0·126
(3) 1 „ „		0·148
(4) 1½ hours „		0·137
(5) 2 „ „		0·112

This shows a very definite rise of 50 mg. per 100 c.cm., reaching its maximum in one hour after the ingestion of the lævulose, and remaining at an abnormally high level for at least two hours.

B. The following is an example of a *severe* degree of liver inefficiency as revealed by the test. In this case the blood-sugar curve is higher and tends to be more prolonged than in the former case.

J. E., aged 46, a severe case of intense jaundice which followed one N.A.B. injection; asthenia and anorexia very marked. On 22/7/21 50 g. lævulose gave the following result (see Fig. 2):—

		Blood-sugar per cent.
(1) Before	50 g. lævulose	0·125
(2) ½ hour after		0·137
(3) 1 „ „		0·192
(4) 1½ hours „		0·154

After four weeks the patient was discharged from hospital, greatly improved. Seen again on 13/9/21 all signs of jaundice had disappeared, the patient was quite well, and had been free from all symptoms for three weeks. The liver-function test was repeated with the following result:—

		Blood-sugar per cent.
(1) Before	50 g. lævulose	0·101
(2) ½ hour after		0·102
(3) 1 „ „		0·110
(4) 1½ hours „		0·106
(5) 2 „ „		0·100

It is interesting to compare these two results, the first denoting a marked degree of liver inefficiency; the second a normal reaction to the test, denoting a restoration of the liver function.

C. The following is an example of an *extreme* degree of liver inefficiency as revealed by the test.

C. L., aged 57. Treated with two courses of silver salvarsan; jaundice appeared ten days after the last injection. Seen on 5/9/21 two weeks after the appearance of symptoms, the patient showed a definite degree of jaundice, with asthenia and anorexia. The symptoms were not so marked as to suggest anything more than moderately severe affection of the liver with a correspondingly good prognosis. On 9/9/21 there was no change in the patient's condition. The liver-function test, using 50 g. lævulose, gave the following result (see Fig. 3):—

		Blood sugar per cent.
(1) Before	50 g. lævulose	0·117
(2) ½ hour after		0·150
(3) 1 „ „		0·141
(4) 1½ hours „		0·164
(5) 2 „ „		0·192
(6) 2½ „ „		0·184

Two days later the patient became extremely ill, and died on 12/9/21. A post-mortem examination was carried out 14 hours after death by Dr. J. F. Taylor, to whom we are indebted for the following report: "The liver shows marked perihepatitis and some diffuse cirrhosis with numerous 'new bile-ducts.' There is general congestion with extensive areas of extreme toxic necrosis with polynuclear infiltration. Free bile-pigment present. Much granular fatty degeneration and crystals of free fatty acid."

As indicated by the figures just given, the result of the test carried out three days before death showed an extreme incapacity on the part of the liver to deal with the lævulose presented to it. The high continued rise, reaching its maximum two hours after the lævulose, and continuing for some time afterwards, presents a more intense picture than we have encountered in any other case.

patients. As has been described above (Cases No. 2 and 3), *we twice induced a severe attack of asthma* in patients by giving too high doses of tuberculin. This mistake now no longer occurs, since we know that only very small doses of tuberculin are necessary, or even advisable. Whether Walker's cure is less dangerous than ours we are not in a position to decide. In the cases where we used it we never saw dangerous or even disagreeable reactions. If, in addition to the tuberculin treatment, injections with autogenous sputum vaccines are given, great care must be taken (as stated by Walker also), since an overdose of vaccine may be dangerous.

Finally, it may be remarked that, in those cases in which the tuberculin test is negative, we still have the chance of finding a sensitiveness to one of Walker's proteins, and such cases can then be treated accordingly. Our number of cases falling into this class is too small to justify a publication of the results, and the same holds for the few cases in which we could not find a sensitiveness with either of the methods. These patients were treated in a different way.

Difficulty of Explaining Effects Produced.

It seems to us that the results obtained with our method are very clear and need little additional discussion. The prominent fact is that, in a very high percentage of cases, the acute attacks of asthma disappear after a few injections. It is far more difficult to give a satisfactory explanation for the effects obtained.

Since we are not able to give a decisive explanation only a few words will be said on this matter. The starting-point of the tuberculin treatment was our supposition that a state of hypersensitiveness to tuberculin might be a factor which raises the susceptibility of patients for allergic or anaphylactic reactions (including asthma and hay fever). This hypothesis is strengthened by the results of the experiments of Ricker and Goerdeler, mentioned above, who found a locally increased sensitiveness to drugs in rabbits with experimentally induced tuberculosis of the omentum. Further support for our hypothesis was obtained, first, from our own observations on increased *serum skin reaction in children suffering from an acute* exacerbation of tuberculosis; secondly, from the fact, revealed during our work, that many patients suffering from asthma or hay fever show exceedingly strong v. Pirquet reaction; and, thirdly, from the fact that in two patients we induced a strong attack of asthma by injecting an overdose of tuberculin. This last observation shows that there certainly exists a relation, whatever its nature may be, between tuberculin reaction and some cases of asthma. This last conclusion is, moreover, strengthened by the result of our treatment.

If it is true that a condition in the human body which gives rise to a strong v. Pirquet reaction also causes an increased susceptibility to allergic reactions, two qualifications must be made. First, the condition which causes a strong v. Pirquet reaction cannot be as a rule an *active* tuberculous process, since in none of our cases was this found, and the sputums of our patients never contained tubercle bacilli. Secondly, tuberculosis (or rather a condition which produces a strong v. Pirquet reaction) cannot be the *only* factor which is able to create a susceptibility to asthma, since 11 per cent. of our asthma patients gave a negative v. Pirquet test.

Conclusion.

If our hypothesis is true, it still remains difficult to explain *why* a state of hypersensitiveness to tuberculin increases the susceptibility for allergic reactions, and why injection of small amounts of tuberculin has a curative effect. We do not want to enter upon further speculation on this point; we only desire to draw attention to the fact that, in our opinion, the tuberculin treatment of asthma has to be carried out with injection of *small* amounts of tuberculin, and that it is unwise in these cases to try to raise the dose very high in order to obtain an immunisation. Research is going on in this institute at the present moment with the aim of proving the correctness of our hypothesis. *The results of this work will be published* later.

We are greatly indebted to the Arlington Chemical Company for their courtesy in placing at our disposal the different proteins used in the sensitisation test.

Note.—After finishing the present paper we read an abstract in the *Journal of the American Medical Association*, Oct. 15th, 1920, p. 1030, of a publication from Pietroforte in *Riforma Medica* (Naples), July 17th, 1920, No. 29, on tuberculin treatment of asthma. Though our work was undertaken independently of Pietroforte, it is only fair to state that the priority of the tuberculin treatment of bronchial asthma belongs to Pietroforte. As far as we are aware he did not extend the treatment to hay fever.

THE STANDARDISATION OF SUSPENSIONS OF RED BLOOD CELLS FOR WASSERMANN TESTS.

BY JOSEPH W. BIGGER, M.D.DUB., D.P.H.,
MEDICAL INSPECTOR, LOCAL GOVERNMENT BOARD, IRELAND.

FROM time to time cases are recorded of a sample of serum having been sent, for a Wassermann reaction (W.R.) test, to different pathologists, some of whom have reported it as positive and some as negative. In bacteriology, as in everything else, mistakes are possible; but apart from these, there remain some cases in which the inconsistencies of the findings are due not to gross error but to differences in technique. Attempts to standardise the W.R. can never be completely successful, as each of the four reagents employed in the test—complement, antigen, amboceptor and red blood cells—is more or less variable. The first three are usually titrated and accurately diluted prior to the test proper, but this is not done in the case of the suspension of red blood cells. Several workers have pointed out the importance of standardising the strength of the suspension used, but up to the present the majority of bacteriologists are content to employ suspensions which contain a known percentage of the deposit of cells obtained by centrifuging, or which are judged, by their appearance, to be of about the usual strength. Neither method is at all accurate, since the volume of deposit obtained from the same volume of blood depends on a number of factors—the type of centrifuge, its rate of revolution, the duration of spinning, &c.—while the judgment of strength by appearance depends on memory, which in such matters is unreliable. The number of cells in each cubic centimetre of the suspensions used by a careful and experienced Wassermann worker in three successive batches of tests was accurately determined and found to be 505 millions, 328 millions, and 484 millions respectively. It is probable that the suspensions used by other workers show variations as great as, or even greater than, these.

In order to determine the effect, on the apparent hæmolytic strength of complement, of variations in the strength of the red cell suspensions, the following experiment was made. A suspension of cells (A) was standardised as described later. Using 0·5 c.cm. of this suspension and 1·0 c.cm. of guinea-pig serum, diluted 1/20, the total volume in each tube being 2·5 c.cm., the minimum hæmolytic dose (M.H.D.) of the amboceptor was determined. The amboceptor was then diluted, so that 0·5 c.cm. of its solution contained 5 M.H.D. Three other suspensions of the red cells were made, B containing 10 per cent., C 50 per cent., and D 100 per cent. more cells than A. The very small amount of lævulose in the blood will produce glycosuria.

With these points in view the advantage of estimating the efficiency of the liver by a method which excludes the interference of the kidney is obvious.

Conclusions.

A valuable indication of the efficiency of the liver can be obtained by estimating the changes in blood-sugar concentration which follow the ingestion of lævulose. In a healthy adult, with a normal liver efficiency, a dose of 50 g. lævulose will produce no appreciable rise in blood-sugar. In a subject with diminished liver efficiency a definite rise in blood-sugar will result from the ingestion of lævulose. The height and length of the "blood-sugar curve" which portrays this rise will be in proportion to the degree of liver inefficiency which is present. The test affords a means of estimating the degree of liver damage in cases of toxic salvarsan hepatitis and other diseases of the liver. The kidney threshold for lævulose is lower than that for glucose and varies in different individuals. The inconstancy of the threshold for lævulose renders the older method of testing liver efficiency by urinary examination inaccurate.

We wish to express out indebtedness to Prof. H. Maclean, Director of the Medical Unit, at whose suggestion this research was undertaken, and to Colonel L. W. Harrison for granting us facilities for investigating certain of his cases.

ON THE TUBERCULIN TREATMENT OF BRONCHIAL ASTHMA AND HAY FEVER.

BY PROF. DR. W. STORM VAN LEEUWEN.
DIRECTOR OF THE PHARMACOTHERAPEUTICAL INSTITUTE OF THE UNIVERSITY OF LEIDEN, HOLLAND;

AND

H. VAREKAMP,
ASSISTANT AT THE INSTITUTE.

IN an investigation published three years ago by de Kleijn and Storm van Leeuwen[1] it was found that patients suffering from bronchial asthma have a disordered purine metabolism analogous to the disorder found in cases of gout. If normal individuals are first kept for some days on a purine-free diet, and are then given on one day an excess of a foodstuff rich in purines (250 g. of sweet-bread), they will excrete the surplus of purine (i.e., about 600 mgm.) in one or two days. Our cases of bronchial asthma, however, either took three or four days for this additional excretion or excreted the surplus of uric acid only partially. As a result of this research we treated asthma patients with a purine-free diet, and, in addition, gave them large amounts of calcium chloride (up to 10 g. daily during five successive days). Though in some cases we got good results, this treatment was often unsatisfactory. During a visit to the United States one of the present authors had occasion to study the work of Chandler Walker[2] in Boston on protein sensitisation in asthma cases. After coming back to Holland we took up Walker's method and tested a number of patients for protein sensitisation Walker's intradermal scarification tests. We had at our disposal about 30 different proteins, including all those which give any likelihood of positive reactions. The tests were applied according to the indications given by Walker, and described by him as follows:—

"A number of small cuts, each about one-eighth of an inch long, are made on the flexor surfaces of the forearm. These cuts are made with a sharp scalpel, but are not deep enough to draw blood, although they do penetrate the skin. On each cut is placed a protein and to it is added a drop of tenth-normal sodium hydroxide solution to dissolve the protein and to permit of its rapid absorption. At the end of half an hour the proteins are washed off and the reactions noted, always comparing the inoculated cuts with normal controls on which no protein was placed. A positive reaction consists of a raised white elevation or urticarial wheal surrounding the cut. The smallest reaction that we call positive must measure 0·5 c.cm. in diameter and any smaller reactions are called doubtful."

In 18 asthma patients tested in this way we found positive reactions in only four cases (22 per cent.). This percentage of positive skin tests accords with the findings of Walker and others; Walker found in 400 asthma patients 78 positive reactions to animal hair and 68 to food proteins; in addition to this he found 33 positive reactions to bacterial protein and 92 to pollen. Sanford some time ago made a preliminary report of protein sensitisation tests made on more than 800 patients in the Mayo Clinic in Rochester; 500 gave negative skin reactions and about 100 showed only doubtful reactions, so that roughly 200 patients, or one-fourth of his cases, showed definite skin reactions.

Relationship of v. Pirquet and Allergic Reactions.

Though in some cases giving positive skin reactions we got good results with specific protein treatment, we deemed it necessary to look out for a mode of treatment applicable to a larger number of cases. In the course of a research on the reactions of normal individuals and patients to intracutaneous injections of various diluted serums, carried out by Landsteiner and the present authors, our attention was drawn to the fact that very often persons who show a strong skin reaction after serum injections also give a very marked tuberculin (v. Pirquet) reaction. This pointed to the possibility of a relationship between the intensity of the v. Pirquet tuberculin reaction and the intensity of allergic reactions—a suggestion strengthened by the following observation:—

In a girl of 15, tested with intradermal injection of 1:10 and 1:100 dilutions of horse serum, swine serum, sheep serum, and rabbit serum, all reactions were negative; on the same day 3 c.cm. of sheep serum were injected subcutaneously. Three weeks after the first injection all reactions, including that to sheep serum, were still negative; thus 3 c.cm. of sheep serum did not suffice to produce a specific sensitisation to this serum. After three weeks—i.e., six weeks after the first injection—skin tests were all very *markedly positive*. On examination the girl proved to have an active lung process of tuberculous origin which had not been manifest on the previous occasions. Her temperature was 38·7° C.

In this case, then, skin reactions were negative and became positive after a tuberculous process had developed, or after a latent tuberculosis had become active.

Once our attention was drawn to the fact that there was probably some relation between a condition of increased sensitiveness to tuberculin and the intensity of allergic reactions, and with the knowledge that many cases of bronchial asthma must be considered as caused by allergic reactions, it was only one step further to suppose a similar relationship to exist between bronchial asthma and sensitiveness to tuberculin, as shown by the v. Pirquet test. Other considerations led to the same view: First, we noticed some time ago that certain cases of hay fever, an illness undoubtedly related from an ætiological standpoint with bronchial asthma, showed extremely strong v. Pirquet reactions; secondly, we had seen a case of hay fever where an intradermal tuberculin test gave an enormously strong reaction, and where the condition of the patient was much improved the next day; which improvement, for lack of any other explanation, had to be ascribed to the action the suspension used (4H) is one which has been found suitable for the W.R. method in use. This method is identical with Harrison's (No. 1 in the Medical Research Committee's Report on the Wassermann test),[2] except that two volumes of sensitised cells are used, the tubes containing:—

Patient's serum (1/5)	.. ..	0·5 c.cm.
Extract (or saline, in control tube)	..	0·5 c.cm.
Complement (three or five doses)	..	0·5 c.cm.
Sensitised cells	.. .. ..	1·0 c.cm.

To sensitise the cells, one volume of S.S. is mixed with one volume of a solution of amboceptor containing 5 M.H.D. in 0·5 c.cm. This strength of suspension will be found to be somewhat weaker than that used by many bacteriologists, but it has been found very suitable for W.R. work as it gives sharp results. If *another strength—say pH—be desired, the standardisation* is carried out as before, but the amount of saline necessary to add to 1 c.cm. of N.S. will be $\frac{x-(p-1)}{p}$ c.cm. If Harrison's method is followed exactly one unit (0·5 c.cm.) of sensitised cells is added to each tube. *This contains one-half unit (0·25 c.cm.)* of suspension. A suitable strength to make the S.S. would be 8H.

In order to test the accuracy of this method of standardisation, samples of sheep's blood were obtained from a slaughter-house at intervals of one or more weeks. *The red cells were washed and two* standard suspensions (4H) of each were made. The number of cells in each was counted, three counts, each of at least 1000 cells, being made and averaged. A Thoma (Hawksley) chamber was used for counting. Table III. gives the results of this control.

TABLE III.

Blood No.	Suspension.	Average of 3 counts (millions per c.cm.).	Average of A and B.	Percentage error of A and B as compared with average of A and B.	Percentage error.
1	A	518	512·5	1·1 %	+ 4·0 %
	B	507			+ 1·8 %
2	A	476	468	1·7 %	− 4·4 %
	B	460			− 7·6 %
3	A	511	497	2·8 %	+ 2·6 %
	B	483			− 3·0 %
4	A	489	503	2·8 %	− 1·8 %
	B	517			+ 3·8 %
5	A	501	497·5	0·7 %	+ 0·6 %
	B	494			− 0·8 %
6	A	502	508·5	1·3 %	+ 0·8 %
	B ·	515			− 3·4 %

Average of the 12 suspensions 498

It will be observed that the greatest error of any pair of suspensions as compared with the average of the two is 2·8 per cent., and that in only one standardisation is the error greater than 5 per cent. when compared with the average of the 12. It *is possible that a certain amount of error may be* introduced by differences in the blood of individual sheep. In some the size of the corpuscle or its hæmoglobin content may be different from what is found in others. A consideration of Table III. would lend some support to this view, but there is no reason *to suppose that such variations should be greater* in the case of healthy adult sheep than in the case of normal men. No divergences which would render this method of standardisation unreliable were revealed in the controls dealt with above. It may therefore be claimed that this method is one which can be recommended as sufficiently accurate for use in the W.R. test. It may be noted that the strength of suspension chosen (4H) corresponds very closely to a count of 500 millions of red cells per cubic centimetre.

Summary.

1. *Methods usually adopted for making suspensions* of red blood cells for the W.R. test are very rough, and the resulting suspensions vary greatly in strength.

2. Such variations may introduce considerable error in the results of the test.

3. A simple and rapid method of standardising red blood cell suspensions is described.

4. This method was controlled by counting the number of cells per cubic centimetre in 12 suspensions, and was found to be accurate.

5. It is suggested that the notation here adopted (in terms of Haldane's solution) might be used to record the strength of any suspension of red blood cells since a new suspension of similar strength could be prepared when required.

SEROUS MENINGITIS.

BY A. GURNEY YATES, M.A., M.D. EDIN., M.R.C.P. LOND.,
PHYSICIAN, SHEFFIELD ROYAL INFIRMARY.

SEROUS meningitis was first described by Quincke[1] in 1893 and a considerable number of cases have since been reported, but the condition does not appear to have received the more general attention which it deserves. Pathologically, the essential condition is an increase in the intracranial pressure due to an excess of cerebro-spinal fluid. This excess is produced, not so much by mechanical obstruction—though the latter may be a factor in certain cases, as when the foramina in the roof of the fourth ventricle are blocked by exudate or old thickening—but by an inflammation of the meninges and ependymal lining of the ventricles which never passes beyond the serous stage. The ventricles are usually distended with clear fluid, but in some instances the fluid is mainly in the subarachnoid space, and there may be definitely localised collections at the base or elsewhere. A remarkable case has just been published by C. E. Reynolds,[2] in which fits of varying type occurred, the variations being due to alterations in the position of the fluid brought about by changes of posture.

Description of Cases of Serous Effusion.

Excluding grossly obstructive cases, such as those due to tumour or obliteration of the large sinuses, cases due to tubercle and syphilis, and non-inflammatory cases secondary to cardiac and renal disease, there still remains a group of cases, acute and chronic, of which a non-purulent inflammatory effusion is the essential feature. Associated with the serous effusion a variety of conditions have been described. Quincke found the ependyma thickened and in some cases granular. P. Merle[3] described inflammatory changes in the meninges and choroid plexus as well as in the ependyma, but he maintained that the last was the most frequent and the most important. In some cases an encephalitis was found in addition, and other conditions described include obliteration of the aqueduct of Sylvius and of the foramina of Monro, and adhesions isolating some part of the ventricular cavity.

Joel[4] described a case secondary to a fœtid discharge from the left ear, which was at first thought to be an extradural abscess, but the only condition found at operation was œdema of the meninges and brain tissue, which recovered completely. W. B. Warrington[5] found in a case secondary to a left-sided otitis merely increased fluid and congestion of the meninges which cleared up completely. In another case he described thickening of the floor of the fourth ventricle by granulation tissue. Nonne[6] recorded two cases, one following injury in which nothing was found except great dilatation of the ventricles, and the other apparently due to mental shock, in which there was hydrocephalus with fresh granulations in the ependyma. Other writers have described similar conditions and microscopically *perivascular infiltration, and in cases of longer standing* fibrosis has been found in the ependyma and pia-arachnoid. A case published by Parkes Weber[7] in 1902 in a woman of 22 showed, in addition to great distension of the ventricles, thickening of the ependyma

---

[2] Medical Research Committee, Special Report Series, No. 14, 1918.

(6) E., typographer, aged 50. Asthma since age of 38; of late years four to five attacks a day, two or three every night. Very dyspnœic; had to give up profession. Has had ambulant treatment with B.B. and P.D., but without tuberculin; afterwards in hospital for three months. In the hospital, condition as before. 26/5/21, tuberculin treatment, ambulatory; 5/6/21, condition improved but not cured; taken into hospital. Tuberculin 1 c.cm. 1 : 100,000, increased to 3 c.cm. 1 : 100,000. During first three days two or three adrenalin injections daily; afterwards free from attacks. 10/6/21, sent home with chronic bronchitis and emphysema (condition much better but not cured); 27/7/21, condition much better. 31/8/21, has had slight attacks. Ordered to fast for two days and after that live mainly on rice and bread with small amounts of protein; condition much better.

(7) G., labourer, aged 40. Has worked in factory with oats for half a year, and since that time has had attacks of asthma which have increased in intensity. Skin reaction with various proteins, *including oat protein*, negative; v. Pirquet + +, ambulatory tuberculin treatment started; 25/5/21, first 1 c.cm. of 1 : 100,000 T.O.A., gradually increased to 3 c.cm. 1 : 100,000. An attack on 10/7/21; no more since that time.

(8) V., commercial traveller, aged 20. Asthma since childhood; last 10 years never free from dyspnœa; very frequent and heavy attacks; severe chronic bronchitis. Skin reaction: dog hair +, v. Pirquet + 30/3/21, admitted to hospital, B.B. and P.D., intramuscular milk injections; condition not much better; 1/5/21, leaves hospital; 8/5/21, treatment with dog hair started; after one month not much success. 8/6/21, tuberculin treatment (ambulatory) started, 1 c.cm. 1 : 100,000, increased till 4 c.cm. 1 : 100,000; no attacks since that time, but chronic bronchitis persists and patient remains dyspnœic; 5/9/21, has had a few severe attacks of asthma. Condition not much bettered since beginning of treatment.

(9) B., married woman, aged 48. Almost daily bronchitis and asthma for 15 years. V. Pirquet +, P.D. and ambulatory tuberculin treatment started. 15/6/21, first dose 1 c.cm. 1 : 100,000 T.O.A., increased to 3 c.cm. 1 : 100,000. After second injection attacks nearly ceased. After third injection no more attacks.

(10) S. I., merchant, aged 28. Asthma from age of one year old, acute attack once a week, lasting two or three days. For a few months B.B. and P.D.; not much bettered. Skin reaction negative, v. Pirquet + +. 29/6/21, admitted to hospital and tuberculin treatment started; first dose 1 c.cm. 1 : 100,000, increased to 3 : 100,000. After first injection one attack. No more since that time. Leaves hospital 10/7/21 cured, with slight chronic bronchitis. Autogenous vaccine. After second injection with 10 million bacteria slight attack of asthma. No further attacks till 30/8/21; one on that day lasting three days, others afterwards. Condition improved after treatment, but not satisfactory.

(11) V., banker, aged 38. Very severe asthma, attacks nearly every day. Not able to sleep in bed for a year. Can only sleep in sitting position; v. Pirquet +. 5/7/21, admitted to hospital and tuberculin treatment started. B.B. and P.D. First dose of tuberculin 1 c.cm. 1 : 100,000 T.O.A., increased to 4 : 100,000. First three days gets one or two adrenalin injections a day, then no more. 8/7/21, completely well; can sleep lying quite flat; 19/7/21, sent home completely cured.

(12) N., schoolboy, aged 13. Asthma since age of 7. about one attack a week lasting one day; v. Pirquet + +; 30/6/21, ambulatory tuberculin treatment started, first dose 0·5 c.cm. 1 : 100,000 T.O.A., increased to 1·5 c.cm. 1 : 100,000. No attacks since beginning of treatment.

Remarks.

From the clinical histories given above it is evident that the most prominent factor of our treatment is the disappearance of the acute attacks of asthma in a very short time. When the acute attacks of dyspnœa disappeared after the first injections of tuberculin one of two conditions remained. Either the patient was completely cured or there was a chronic bronchitis left. It may be stated at once that even in the latter case the improvement was marked. Most of the patients considered themselves to be cured and took the remaining bronchitis very lightly. Our attempts to cure this also were much facilitated by the subsidence of the acute attacks of dyspnœa. It is hardly necessary to mention that in cases of long duration, where emphysema had developed or the heart had become weak, no complete recovery could be obtained.

In tabulating the results of the tuberculin treatment 8 cases, including the 12 detailed above, the ts could be divided into four groups, as follows: Group I. contained 18 patients who are completely cured; Group II. contained four patients whose acute attacks of asthma completely or almost completely disappeared, but where a chronic bronchitis remained, which though very much improved was not completely cured; Group III. contained five patients whose condition was improved by treatment, but who were not cured, some having dyspnœa due to bronchitis or a weak heart, and three having occasional attacks of asthma, acute but never so severe as before treatment; Group IV. contained one case (No. 8 in the above list) where tuberculin treatment failed to improve the patient's condition. Roughly speaking, Groups I. and II. (78 per cent. of all cases) contained cases where tuberculin treatment did all that could be expected. Group III. (18 per cent.) contained cases which were decidedly improved; Group IV. contained the failures (about 4 per cent.).

Late Results.

It is not possible to state whether the cures obtained will be lasting. We have only had one relapse till now, but our first case dates from 15 months ago and the latest case only two months. It is to be expected that some relapses may occur, and if this be the case we shall treat them again. Though our time of observation is short, and though we cannot give any guarantee that all our patients now considered to be cured will remain so, we feel justified in publishing our results; for even if all our patients relapse within a year, we should still consider that they had greatly benefited by the treatment. Most of them were in a deplorable condition on coming under our care, having been dyspnœic for years, some of them for decades. Some had not had one quiet night for a long time; three were in danger of becoming morphinists; others could only do their work by injecting themselves with adrenalin or by smoking asthma cigarettes every two hours; four were in danger of having to give up their professions. All these people were brought to a normal or almost normal life again by a cure of 10–14 days' duration; and certainly their state of health (especially their bronchitis) must be considered as improved, even if relapses occur.

As has been stated above, we only started our tuberculin treatment after having tried Chandler Walker's specific protein therapy, and it is fair to consider how far we were justified in preferring our therapy to his. We must here state that we value Walker's work highly, and we are of the opinion that his treatment may be very beneficial. Walker obtains a relief of asthma in about 80 per cent. of cases, showing a specific skin reaction to proteins; we also record relief in about 80 per cent. of our tuberculin cases, so that, in this respect, there is not much difference between his results and ours. There is, however, one factor which gives a very decided advantage to our method. According to the statistics of Sanford (*vide* above) sensitisation to animal and food proteins is only found in 25 to 30 per cent. of the cases; Walker finds positive tests in 48 per cent. of his cases, but in this figure are included a number of cases with reactions to pollen only, belonging to the type of asthma occurring only in summer. Since nearly all our cases had attacks of asthma during the whole year, only 20 to 30 per cent. could have been expected to be benefited by Walker's treatment. (In reality our number was still lower.) On the other hand, from our entire number of asthma patients (34) the greater part (30)—i.e., 89 per cent.—showed a positive tuberculin reaction, so that all these could be treated according to our method.

A minor advantage of this method is that the necessary material, tuberculin, can everywhere be had in any amount, whereas the specific proteins necessary in the Walker treatment are only manufactured—so far as we know—in the United States; work with Walker's proteins in Europe is therefore handicapped to a certain extent.

It may be regarded as a disadvantage of our method that the administration of tuberculin is not a trivial matter, and requires great care and supervision of the

After the operation the pain completely disappeared for a time and the pulse-rate increased to normal, but otherwise his state remained the same. On the 16th slight paresis of the right external rectus was noticed, and a few days later the optic neuritis had become severe. There were now four dioptres of swelling and some hæmorrhages. The pulse-rate was now more rapid, varying between 80 and 120, and the deep reflexes were absent. The vision was still 6/6. As no improvement occurred, and the sight appeared to be threatened in the patient's only eye, he was trephined on May 17th over the right temporo-sphenoidal lobe by Prof. A. M. Connell. On exposing the dura no pulsation was seen and when the dura was opened the pia-arachnoid was found to be congested and presented a bright red granular appearance. The convolutions were distinctly flattened. On exploration a deep resistance was felt, apparently due to the distended lateral ventricle. This was tapped and considerable amount of fluid withdrawn. The pulsation of the brain immediately became normal, the dura was brought together, and the wound closed.

Following operation recovery was rapid. On June 24th the wound was completely healed, there was no hernia at the site of operation, and the patient felt perfectly well. His vision was normal and the optic neuritis had completely gone. He is now at work, and except for an occasional slight pain similar to the one he had prior to the onset of his acute symptoms he is perfectly well.

In some respects this latter case at first resembled frontal sinus disease, but this was finally excluded at the first operation. With the occurrence of a slow *pulse, optic neuritis, and a sixth nerve palsy it* became evident that some condition causing increased intracranial tension was present, and the nature of the first fit suggested a localisation in the right temporo-sphenoidal lobe irritating the auditory centre. The acute onset was against its being a tumour, and the patient did not present the foul tongue and general toxæmic state of a cerebral abscess. The absence of pyrexia was strongly against suppurative meningitis or sinus thrombosis, and the possibility of its being a serous meningitis was confirmed by the finding of congestion of the meninges at the site of operation and the rapid recovery following decompression and the evacuation of fluid under pressure from the lateral ventricle. The cause of the condition was not clear; it was difficult to associate it with a slight injury 17 years before, and it seemed to be more likely that an infection of low virulence had spread to the interior of the cranium, possibly from the slight old-standing disease in the ethmoid region.

Remarks.

It would appear to be worth emphasising that in cases in which the signs and symptoms of increased intracranial tension develop acutely serous meningitis should be kept in mind and a search made, first for acute or chronic otitis, and if this is not found, for some other cause, such as inflammation in the accessory sinuses of the nose or some more generalised source of infection. The diagnosis from the more grave acute cerebral lesions—abscess, sinus thrombosis, purulent meningitis—may be very difficult. In serous meningitis however, one does not usually find the rigors and high fever of a sinus thrombosis, the foul tongue, the general toxic appearance, and the leucocytosis of a cerebral abscess, and a lumbar puncture will usually distinguish a purulent meningitis. In the more chronic cases in adults (pseudo-tumour) the difficulty is probably greater, because the similarity clinically between a tumour without definite localising signs and a slowly developing serous meningitis may be very close indeed.

The prognosis of the acute cases is much more favourable than that of the other acute conditions which lead to an increased intracranial pressure, and many recorded cases have recovered. The first essential in treatment is to find the primary source of infection and to deal with it in the most appropriate manner. The free drainage of pus from the temporal bone may be all that is needed to bring about the rapid disappearance of all cerebral symptoms. In some cases it is true that serous meningitis has developed after such operative interference, a course of events which recalls *the occasional occurrence* of disseminated tubercle after an operation on a localised focus, but this consideration should never deter the surgeon from operating when the primary condition demands it; it is rather an argument for the freest possible drainage, especially as it is likely enough that such a case would, if left, develop some more serious cerebral complication.

If the intracranial pressure does not quickly subside steps should be taken to relieve it, and in the more acute cases this can most readily be done by lumbar puncture, a procedure which is also of the greatest possible value in the diagnosis. When serous meningitis *is the only intracranial lesion present it is not*, as a rule, necessary to open the dura. In the more chronic cases, however, which may closely simulate a cerebral tumour—a condition in which lumbar puncture is known to be dangerous—greater caution is desirable; until the diagnosis can be placed upon a surer footing it is a wise rule to refrain from lumbar puncture, and to resort to decompression in cases where a tumour cannot with reasonable certainty be excluded, and probably also in those where epileptiform convulsions with unconsciousness have occurred. It was this consideration which led me to refrain from doing a lumbar puncture in the second of the two cases described above.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

◆

A CASE OF
PARTIAL PYLORIC STENOSIS
(HYPERTROPHIC): FINNEY'S OPERATION.[1]

BY R. P. ROWLANDS, M.S. LOND., F.R.C.S. ENG.

THE case here recorded is a typical instance of partial stenosis due to spasm and hypertrophy of the pyloric sphincter.

The patient, G. W., a male aged 32, has supplied the following details of the early history of the case: "Pain began about nine years ago (1912) on and off, after food, until 1915, when I first started vomiting, having about three attacks in that year lasting a week each time they occurred. In the following year (1916) my service in the army began, and from then onwards I had pain and vomiting after the least exertion. I was admitted to hospital at various times with these attacks as gastritis, and after rest and light diet was much better. After a short time they would recur. Since my discharge in 1919 they became more frequent—about every month—lasting, on an average, 10 days to a fortnight, until my operation was performed. Symptoms: Pain about two hours after food, which would increase until I vomited, when pain became less. This would occur three or four times a day for from 10 to 14 days. Vomit was sour and curdled and in large quantities."

I first saw the patient at the Second London Hospital in June, 1918, when I removed his appendix, having felt the stomach, duodenum, and gall-bladder from the wound and found no abnormality. X ray examination of the stomach was negative. I next saw him in June, 1921, when the frequency of his attacks and the amount of vomiting had increased, and he had wasted considerably. The frequent recurrence of symptoms threatened to spoil his life and lose him his appointment as clerk. He was therefore admitted into Guy's Hospital for further investigation. Chemical analysis showed no abnormality in the gastric function. X ray examination showed a hypotonic, very dilated stomach with delay, but no evidence of gastric or duodenal ulcer or pyloric stenosis. I concluded from this that the patient had

---

[1] Shown at a meeting of the Clinical Section of the Royal Society of Medicine on Nov. 11th, 1921.

M.H.D. of the complement was accurately determined for each cell suspension. Each tube contained—

Amboceptor (5 M.H.D.)	0·5 c.cm.
Cell suspension (A, B, C, or D) ..	0·5 c.cm.
Guinea-pig serum	x c.cm.
Saline	(1·5–x) c.cm.

The tubes were heated in a water-bath at 37·5° C. for two hours and examined. The smallest amount of guinea-pig serum which produced total hæmolysis was taken as the M.H.D. of the complement in the case of each cell suspension (Table I.). The results of a similar experiment are recorded in Table II.

TABLE I.

Cell suspension.	Relative number of cells per unit volume.	M.H.D. of complement.	Relative M.H.D.
A	100	0·0105 c.cm.	100
B	110	0·0115 ,,	109
C	150	0·0175 ,,	166
D	200	0·0250 ,,	238

TABLE II.

Cell suspension.	Relative number of cells per unit volume.	M.H.D. of complement.	Relative M.H.D.
A	100	0·009875 c.cm.	100
B	110	0·0102 ,,	103
C	125	0·0135 ,,	137
D	150	0·0155 ,,	157

It is clear from these results that variations in the strength of suspension used exercise a marked effect on the apparent strength of complement. If the M.H.D. of the amboceptor had been found for each cell suspension, the differences in the M.H.D. of the complement would probably have been less, but it must be remembered that it is not usual to titrate amboceptor on every occasion on which a batch of serums is tested. In general the M.H.D. is ascertained when a new amboceptor is brought into use and, on subsequent occasions, dilutions containing three or five times this amount are employed.

Possible Variations of Results.

Now consider two bacteriologists, X and Y, who are performing W.R. tests, using the reagents employed for the experiment recorded in Table I. X uses cell-suspension A, and Y uses cell-suspension C. X finds the M.H.D. of complement to be 0·0105 c.cm., and makes two dilutions, one containing 0·0315 c.cm.—i.e., three doses—and the other 0·0525 c.cm.—i.e., five doses—in 0·5 c.cm. Y finds the M.H.D. to be 0·0175 c.cm., and his three-dose dilution contains 0·0525 c.cm., while his five-dose dilution contains 0·0875 c.cm. of guinea-pig serum in 0·5 c.cm. The results obtained by X and Y in testing a batch of serums are bound to be discordant, since the three-dose dilution of Y contains the same amount of serum as the five-dose dilution of X. Probably the two will agree as to many of the serums which are frankly negative or strongly positive, but some of X's strong positives will be recorded by Y as positives, while Y will find many of X's positives or weak positives to be negative.

It is unnecessary further to labour the point that variations in the strength of the cell suspension may cause errors in the results of the W.R. test. It follows, therefore, that some effort should be made to obtain suspensions of approximately constant strength, especially if this can be done without unduly adding to the labour of the test. Probably the most accurate method of standardising would be by counting the number of cells contained in a known volume of a suspension and then diluting this until it contained a definite number, previously decided upon, in each cubic centimetre. This method would, however, be tedious, and—unless the counts were carefully done, and duplicated or triplicated—liable to considerable error. Lewis[1] has advised a method of weighing a known volume of suspension, contained in a specific-gravity flask, and, by comparing its weight with the weight of equal volumes of saline of a standard suspension, finding the amount the new suspension must be diluted to produce a standard suspension. We do not think that this method will be widely accepted by bacteriologists. It necessitates the bringing of the specific-gravity flask and suspension to a constant temperature of 60° F. in a water-bath, and accurate weighings in a sensitive chemical balance, which is not always available in bacteriological laboratories.

A Colour Method of Comparison.

In the method here proposed, the colour of the carboxyhæmoglobin produced by treating the suspension of red cells with water and passing carbon monoxide gas is compared with that of the standard tube of a clinical hæmoglobinometer. This method was considered by Lewis, but abandoned, "principally owing to the error inevitably introduced in the final colour matching." It is believed, however, that the method is capable of a considerable degree of accuracy, as will be shown later.

The ultimate standard adopted was the carboxyhæmoglobin solution of a Haldane's hæmoglobinometer. The advantages of using such a standard are obvious; it is constant, easily obtainable, and easily renewable. The standard suspension of cells (S.S.) decided upon was such that when one part of it was mixed with three parts of water and CO passed through the mixture, the resulting solution of carboxyhæmoglobin was of exactly the same tint as that in a Haldane's tube when examined in the comparison tube of the hæmoglobinometer set. Since the standard suspension is four times as rich in hæmoglobin as Haldane's solution, its strength can be conveniently described as 4H. It may here be remarked that this system of notation is a convenient one to use in connexion with any work on suspensions of red blood cells. If a particular suspension of cells be tested and its strength recorded as nH, it is possible at any time or in any place to make a fresh suspension of the same strength.

Technique of Standardisation.

The technique of standardisation is as follows:—

1. A suspension of cells (N.S.) is made which is stronger than the one required.

2. 1·0 c.cm. of N.S. is measured accurately with a 1 c.cm. pipette into each of six or eight clean dry test-tubes—(*a*), (*b*), (*c*), (*d*), &c.

3. To (*a*) add 3·0 c.cm. of water, to (*b*) add 4·0 c.cm., to (*c*) add 5·0 c.cm., to (*d*) add 6·0 c.cm.

4. The contents of each tube are mixed and coal-gas bubbled through by means of a fine glass tube, until the carboxyhæmoglobin colour is fully developed. A portion of each is transferred to the comparison tube of a Haldane's hæmoglobinometer set, and its colour compared with that of the standard tube. Some of the dilutions will be found to be too dark in colour and some too light. Suppose (*a*) and (*b*) are too dark and (*c*) too light. (It is not necessary to wash out and dry the comparison tube after each dilution is tested. It is quite sufficient to empty it, shake it out, and rinse with a small quantity of the next dilution to be tested.)

5. To (*e*) add 4·5 c.cm. of water, mix, pass gas, and compare. Suppose (*e*) is too light.

6. To (*f*) add 4·2 c.cm. of water, mix, pass gas, and compare. Suppose (*f*) is just too dark.

7. To (*g*) add 4·3 c.cm. of water, mix, pass gas, and compare. Suppose (*g*) exactly matches the standard tint.

It is then evident that 1 c.cm. of N.S. + 4·3 c.cm. of water gives a solution containing exactly the same amount of hæmoglobin as Haldane's. The amount which the N.S. must be diluted to produce S.S. can now be calculated. In order to save trouble a formula may be used. If x c.cm. is the amount of water necessary to add to 1 c.cm. to give Haldane's tint, $\frac{x-3}{4}$ c.cm. of saline must be added to each 1 c.cm. of N.S. to produce S.S. = 4H. In the example given, x = 4·3 c.cm., so 0·325 c.cm. of saline must be added to each cubic centimetre of N.S., or 13 c.cm. to 40 c.cm.

Since the whole operation of preparing a standard suspension takes about 10 minutes, it does not add unduly to the time necessary to perform a W.R. test. No difficulty was experienced in colour matching, and it was found possible to determine the value of x to the first decimal place with accuracy. An amount of 0·1 c.cm. greater than x was obviously too light in colour and 0·1 c.cm. less too dark. The strength of

Medical Societies.

NORWICH MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases and Specimens.

A CLINICAL meeting of this Society was held on Dec. 6th at the Norfolk and Norwich Hospital, Dr. WILLIAM WYLLYS, the President, being in the chair.

The PRESIDENT showed two cases, the first being that of a woman, aged 43, who had been quite blind from chronic secondary glaucoma for several years. The tension in the affected eye was +2, and she had external strabismus. There was considerable pain and much irritation of the other eye, not amounting, however, to sympathetic ophthalmia. The President said that he had decided to enucleate the eye, and with some diffidence, on account of the rigidity of the tissues, inserted a Mules's globe and an artificial eye. The result was most satisfactory, as after the operation the irritability of the sound eye subsided; he pointed out that the movements of the artificial eye were excellent, and the appearance from a cosmetic point of view most satisfactory.—Mr. A. J. BLAXLAND expressed some doubt as to the permanence of good results from a Mules's globe, but the PRESIDENT said that if the effect appeared to diminish he would not hesitate to insert another Mules's globe, and gave instances of cases where he had done so.

The PRESIDENT brought forward the second case for diagnosis. The patient was a girl, aged 11, in whom oblique illumination of the left eye showed a film with numerous small opaque dots scattered over it, the condition in his opinion being a persistent pupillary membrane. The patient had not noticed the defect herself, but examination by a school medical officer showed the sight in the right eye to be $\frac{6}{6}$, while that in the left was $\frac{6}{60}$. The condition was very well seen with the aid of a Collins's loop, the use of which was demonstrated.—Dr. G. MAXTED expressed the opinion that the condition was inflammatory, probably of intra-uterine origin.—The PRESIDENT said that, after hearing Dr. Maxted's view, he was disposed to agree with him.

Dr. H. J. STARLING showed two cases, the first being a case of disseminated sclerosis with coincident aortic and mitral disease in an ex-soldier about 25 years of age. The disease did not seem to be progressive, as the patient had been in the same condition for some time, but the incoördination of the hands had considerably improved. There were no tremors. Nystagmus was not marked, but increased after exertion. There was no typical scanning speech unless the man got excited. The abdominal reflexes were absent, while there were exaggerated knee-jerks and ankle clonus. Dr. Starling's second case was a man with coarctation of the aorta, who had been discharged from the army with V.D.H., and who now complained of præcordial pain and dyspnœa; he had a systolic blood pressure of 218 and a diastolic pressure of 124. No blood pressure could be obtained from the femoral circulation. The collateral circulation was carried on by various tortuous arteries, which had been outlined on the patient's body. To compare with this case Dr. Starling exhibited a specimen of the aorta, showing the lesion diagnosed in the clinical case. This latter patient had died from hæmorrhage in the brain, and the condition of the aorta was discovered post mortem. The specimen showed clearly a marked stenosis of the posterior part of the artery beyond the origin of the left subclavian, at the site of the ductus arteriosus.

Dr. F. W. BURTON-FANNING brought forward a case of diabetes insipidus in a young boy which had been completely controlled by pituitrin. The patient suffered from thirst, loss of weight, and weakness, and passed an enormous quantity of urine—100 to 150 oz. in the 24 hours, with a specific gravity of 1001–1002. After a hypodermic injection of 1 c.cm. of pituitrin the quantity of urine decreased to about 50 oz. in 24 hours, and the specific gravity rose to 1015. Pituitrin by the mouth had no effect. Altogether ten injections had now been given with the same effect every time. The condition appeared to be due to some defect of the filtering power of the kidneys, resulting in an inability to excrete a concentrated urine. There was also increased carbohydrate tolerance. The injections of pituitrin caused a rise of temperature and an increase in the secretion of urea. The question of treatment of such cases by transplanting of pituitary gland substance had been discussed, but as it would be necessary to use a human pituitary gland Dr. Burton-Fanning feared that a remedy could not be looked for in that direction.

Mr. BLAXLAND showed a case of dislocation of the hip which had occurred in a boy of 14 after a rather mild form of septic infection causing subacute epiphysitis of the upper end of the femur. Mr. Blaxland also showed: (1) a malignant papilloma of the kidney removed from a man of 35, whose only symptom was painless hæmaturia; (2) carcinoma of kidney removed from a man of 45, whose main symptom was painless hæmaturia.

Dr. MAXTED showed an unusual form of congenital syphilitic disease of the eyes in a girl of 6 years.

Mr. T. W. HANCOCK showed a specimen of early carcinoma of the pylorus before ulceration.

Dr. H. MUIR EVANS showed (1) an annular growth of transverse colon, in which resection was followed by lateral anastomosis; (2) a new growth of the ileum near the ileo-cæcal lock. Resection and an end-to-end anastomosis was performed.

BRISTOL MEDICO-CHIRURGICAL SOCIETY.

A MEETING of this Society was held on Dec. 14th, Mr. C. H. WALKER in the chair, when Prof. I. WALKER HALL gave an account of some work on

The Rôle of Dilute Acids in Infection,

carried out by him in association with Dr. A. D. FRASER. After an explanatory introduction dealing with hydrogen-ion concentration (pH), Prof. Hall proceeded to consider the means whereby the general neutrality of the body was maintained, especially with regard to the local variations of acidity in the alimentary tract, muscles, kidney, &c. He pointed out the necessary changes in pH values in local infections, and that body cells demanded an environment containing between 0·000,001 and 0·000,000,01 g. of hydrogen ions per litre if a satisfactory response to infection was to be made. As, however, this condition might be reached by a mixture of tissue acids such as lactic, phosphoric, sulphuric, and carbonic, Prof. Walker Hall considered in detail the effect of these and other acids possessing a low dissociation constant, especially with regard to the action of the undissociated portions. He showed that not only were red and white corpuscles extremely sensitive to the minute pH changes associated with the very dilute quantities of acid in the blood, but that they had to meet less balanced conditions in the lymph where "buffer" action was less complete. He then related the results of his experiments on the growth of bacteria treated with quantities of acid equivalent to those obtaining in the tissues, and demonstrated the catalytic action of the H ions on the one hand and the retarding influence of the undissociated portions on the other. By the application of these observations Prof. Hall said he had been able to improve materially the technique of blood cultures, and the diagnosis of diphtherial infection. He also alluded to the restraining effect of the monobasic fatty acids on the growth and alkalinity production of diphtheria bacilli, and expressed the hope that his findings would lead to better prophylaxis and decrease in "carriers." The period required for the diagnosis of tubercle and the virulence of micro-organisms had been altered by changing the pH of cellular and round-celled infiltration, mainly perivascular in distribution. The ependyma of the fourth ventricle was mainly involved.

It is evident that such conditions may lead on the one hand to increased production, and on the other to defective absorption of the cerebro-spinal fluid, and in this way bring about an internal hydrocephalus, which is clinically the essential feature of the disease. In an acute form it occurs associated with middle-ear disease in children. J. S. Barr and J. Rowan [8] found optic neuritis in 11 out of 160 cases of suppurative otitis, and in a further 30 there were vascular changes in the fundus, not amounting to optic neuritis, but sufficiently definite to suggest an increased intracranial pressure. It may also follow inflammatory conditions in the nose and accessory sinuses, the acute fevers, and gastro-intestinal infections. The case above referred to described by Parkes Weber followed two attacks of erysipelas of the head, and Quincke has also described a case which presented the same sequence of events. In a certain number of cases the origin has remained obscure, and in one or two instances it has been attributed to mental shock.

This group of cases is thus of very varying ætiology, and consists of cases of serous effusion within the skull, analogous, as Parkes Weber has pointed out, to a serous effusion in the pleura or pericardium. It brings into line cases of infantile hydrocephalus which are probably at the outset inflammatory, cases of chronic internal hydrocephalus in the adult—which often simulate an intracranial tumour—and the more acute cases which may simulate such conditions as purulent meningitis, cerebral abscess, and sinus thrombosis. The most characteristic symptoms are those of cerebral compression, headache, optic neuritis, vomiting, slow pulse, and altered mentality. The onset may be abrupt or gradual, and in the acute cases there is sometimes fever, but it may be difficult to say how far this is due to the serous effusion and how far to the primary disease. Somnolence is frequent and there is sometimes coma. Diplopia, strabismus, and nystagmus are frequently found. Nystagmus is probably due in otitic cases to disease of the labyrinth, and the diplopia to paresis of the external recti. Symptoms referable to more localised interference with cerebral function occur in some cases, such as monoplegia, hemiplegia, and Jacksonian attacks. The knee- and ankle-jerks are often diminished and sometimes absent. Cervical rigidity is also of frequent occurrence; it is usually slight and unaccompanied by retraction of the head. On lumbar puncture the cerebro-spinal fluid is clear, under considerably increased pressure, and usually sterile. On chemical and cytological examination it is often normal, but there may be a lymphocytosis, an increase in protein content, and an absence of the normal reduction of Fehling's solution.

Variability in the severity of symptoms from time to time is frequently observed, a fact of some value in diagnosis, and also of interest in connexion with Barr and Rowan's observation that the optic neuritis is less liable to lead to atrophy and blindness than the optic neuritis of a cerebral tumour. Remissions in severity of pressure would conceivably lessen the tendency to permanent changes in the optic nerve, and such remissions would be more likely to occur when the pressure is due solely to fluid than when it is due to a solid growth. This observation was based entirely upon a study of otitic cases, which are usually acute, but T. R. and E. E. Glynn [9] published a case in which very severe symptoms, including optic neuritis with almost complete blindness and serious mental impairment, lasted for nearly five years, and which recovered completely and regained normal vision after a spontaneous discharge of cerebro-spinal fluid from the nose. On the other hand, total blindness may result quickly. Parkes Weber quotes a case in which total blindness came on within three months of the onset of the illness.

Cases Illustrative of Acute Form.

The following two cases recently under my care illustrate the more acute form of the disease. One was due to acute otitis in a child, the other of uncertain origin.

CASE 1.—A boy, 7 years of age, entered hospital on March 5th, 1921. A month previously he had been suddenly seized with vomiting, earache, and a slight purulent discharge from the left ear. Within a few hours the discharge ceased and the vomiting and earache abated, but he developed a stiff neck. The muscles on the left side of the neck were tender and the head was drawn to that side. This also disappeared in a few days, but he did not return to normal health. He was pale, somnolent, sweated a good deal, and complained of earache and occasional headache. There was occasionally a slight evening rise of temperature. A trivial blow on the head some months before, and measles when four months old, were the only points to note in the previous history.

Examination revealed a slight fulness around and below the left mastoid process and distinct tenderness on pressing the bone. A tender gland could be felt just behind the angle of the jaw. There was no discharge from the ear but the tympanic membrane was congested. Examination of the optic discs showed commencing optic neuritis. There was no head retraction, the stiffness of the neck had gone, and Kernig's sign was absent. The knee- and ankle-jerks were diminished and the plantar reflex was normal. He was pale and listless and looked distinctly ill. There was no diplopia. During the next few days there was a slight irregular pyrexia never exceeding 100 and the pulse varied from 60 to 110. The leucocyte count was 11,000. After five days the temperature subsided and the pulse became slower, keeping steadily between 60 and 70. At the same time the mastoid tenderness and tympanic congestion became appreciably less. There was no improvement, however, in the general condition, and the optic disc in each eye showed a swelling of two dioptres.

On March 17th a lumbar puncture was done; the fluid was under greatly increased pressure and was clear. It was sterile and negative to the Wassermann test. There was no increase of protein, and it reacted normally to Fehling's solution. It contained six lymphocytes per c.mm. Following lumbar puncture the pulse rose and the general condition improved. Five days later the optic neuritis had gone and the patient was discharged on April 1st apparently in normal health. When seen recently he was perfectly well.

CASE 2.—This case, also recently under my observation, presents several features of unusual interest. A man, 24 years of age, a bootmaker by occupation, was admitted to hospital on March 27th, 1921, complaining of intense pain in and around the right eye and to some extent also at the back of the head. He had double pneumonia two years previously and an injury resulting in the loss of the left eye in childhood. He also had a slight scalp wound in the right parietal region 17 years before. He had slight pain behind the right eye occasionally for about a year but it had never interfered with his work. He was taken suddenly ill on March 12th whilst sitting talking in a friend's house. He was noticed to look queer and said he heard some music which seemed to come from a cupboard on his left-hand side. He described it afterwards as being like "a lot of bands playing." He almost immediately lost consciousness and the head and eye deviated to the left. There were slight movements of both legs and he went very pale. In a few moments he recovered and went to see a football match, but on his return he had another attack which was similar to the first one, except that he heard no music. The head and eye deviated to the left as before. Following upon this he had a frontal headache of moderate severity for a fortnight, and then began to have extremely severe pain around the right eye and in the occipital region, and the pulse was noticed to be slow. He vomited once only on the day before admission to hospital.

On examination there was well-marked tenderness over the right frontal sinus as well as over the lower orbital margin, and the eye itself was tender. Transillumination of the right frontal sinus was indefinite, but there were some patches of muco-pus in the region of the right middle turbinal. The pupil was large but reacted normally to light. The optic disc showed no change, the vision was 6/6, and there was no paralysis of any of the cranial nerves; the socket of the left eye was healthy and the ears were normal. The pulse was 50, the temperature normal, and so far as could be ascertained there had not been at any time any pyrexia. The patient was mentally alert, all the deep reflexes were diminished, and there was no rigidity. Kernig's sign was not present. The tongue was clean, the breath was not foul, and he was neither emaciated nor constipated. The urine was normal and the blood gave a negative Wassermann reaction. The condition remained unchanged for several days, the temperature being normal and the pulse varying between 45 and 55. On April 6th commencing optic neuritis was observed, and on April 8th the right frontal sinus was opened by my colleague Mr. W. S. Kerr as the very definite and localised tenderness suggested the possibility of a sinusitis. The sinus, however, was found to be perfectly healthy.

the bacteriological examination of water is dismissed in six pages. Although the isolation of *Bacillus coli* is described, streptococci and *B. welchii* are not mentioned.

Dr. Giltner states that his aim has been to make the book a guide to general microbiology, leaving the particular fields of dairy, soil, water, medical, and other phases of bacteriology to special manuals. It is reliable and, on the whole, up to date; the newer methods for cultivating anaerobes used in this country are, however, omitted. A good account of hydrogen-ion concentration methods is given in the appendix.

Within its self-imposed limits the book is a valuable one. The student who has conscientiously worked through it will be equipped with a knowledge of bacteriological technique and should be well prepared to utilise his training in any special field he may select.

Cardiac Disease.

Original Observations and Theories on Cardiac Disease and the Normal Heart. With a Note on Alcohol. By Michael B. Shipsey, M.B., B.Ch. Birm. Birmingham: Cornish Brothers, Ltd. Pp. 40. 1*s.* 3*d.*

The author of this brochure has attempted the impossible. In the space of 36 small pages, subdivided into 21 sections, he flouts many of the theories and principles accepted by the majority of modern physiologists, physicians, and cardiologists, substituting original and, in some cases, quite ingenious theories of his own. But, doubtless owing to lack of space, he does not attempt to supply proofs of these theories. Dr. Shipsey's views on the mechanical aid rendered by the respiratory system are quite reasonable. It is on the question of the function of the myocardium in health or disease that his views are so unusual, most of them being far from conclusive, especially in the light of recent experimental research. The fact that Dr. Shipsey "believes that he can hear the ventricles contract about a fiftieth part of their full extent" leads one to suppose that either he must have abnormally acute sense of hearing or that he brings a powerful imagination to bear upon his cases during examination. Slight changes in the character of the heart sounds appear to mean more to him than to the average medical man. Dr. Shipsey discusses diagnosis, prognosis, and treatment, including the value of alcohol in heart cases, on broad lines, and rightly emphasises the psychological factor in such cases. But while his book may stimulate free scientific thought, it cannot be considered as likely to be of great value to medical practitioners as a whole.

Les Nouvelles Méthodes d'Examen du Cœur en Clinique. Par R. Lutembacher. Paris: Masson et Cie. 1921. With 138 illustrations. Pp. 186. Fr.20.

In this short but most interesting volume Mr. Lutembacher has demonstrated clearly how much our knowledge of cardiology has been augmented by methods other than those employed in ordinary clinical examination. His book is divided into two parts, in the first of which, after a brief description of different types of polygraphs and of the results attained by their use, he describes and illustrates the various abnormalities which may occur in the myocardium during any period of its intricate cycle. The cardiographic records are so good that for anyone accustomed to reading cardiograms there is hardly a need to refer to the text in this section. The uninitiated will find the descriptions of the different forms of cardiac abnormality so clear that they will find no difficulty in following the argument. The chapter on electrocardiography, owing to its extreme brevity, shows up in rather marked contrast to the sections dealing with the polygraph. We would welcome a further publication by Mr. Lutembacher dealing with the subject more especially from the electrocardiographic standpoint.

In the second part of the book an attempt is made to show what valuable additional knowledge may be provided by radioscopy. In place of the actual radiograms the author substitutes diagrams of the outline of the heart and great vessels, and in each case a photograph of the external appearance of the heart is placed side by side with the radiographic outline. He is careful to emphasise the fact that radioscopy should not take the place of other methods of examination, but he shows how helpful it may sometimes be in certain forms of disease of the heart and the great vessels. Although it is usually impossible for the general medical practitioner to carry out such work himself, he should be acquainted with at least the more common forms of cardiographic and radiographic records, for it is becoming evident that a thorough and exhaustive investigation of the cardiovascular system can be completed only after combined clinical and graphic examinations have been carried out. Mr. Lutembacher in no way belittles the value of clinical examination; in fact he shows how several types of arrhythmia can be diagnosed by clinical methods alone. On the other hand, he is able to prove beyond doubt that some of the abnormalities of excitability or conductivity of the heart muscle, though they give similar clinical signs, produce cardiographic records which are quite dissimilar in character, and which can be interpreted correctly only after careful measurement of the waves, as they appear in the arterial and venous tracings. The book will appeal to all working at diseases and disorders of the heart.

Fasting and Man's Correct Diet.

By R. B. Pearson. Chicago, Illinois: Published by the Author. 1921. Pp. 153.

We do not quarrel with Mr. Pearson's main views on fasting, although fasting is not a panacea, but remarks such as the following should only be made by one who is secure himself from the charge of gross ignorance: "In the writer's opinion it is utterly astonishing that the so-called 'Regular' school of allopathic physicians, as represented by the American Medical Association, should be so profoundly ignorant of the laws of Nature with which they have to deal as they are at present." There is no body of men more profoundly conscious of their own limitations than medical men, and the more skilled and cultivated they are the more they feel how little they know. But it ill becomes a writer who shows such abysmal ignorance as Mr. Pearson often does to carp at other men's ignorance. Mr. Pearson thinks that "germs are scavengers, that they never caused any disease whatever"; he believes that both putrefaction and fermentation are purely chemical actions and not caused by any germ or minute organism; and he makes the following remark after talking about the sterilised culture media used in bacteriology: "Why not try keeping a few 'preparations' at this temperature *without inoculation with bacteria*, and see if they don't decompose just as fast and produce just as much 'toxin' material as the preparations inoculated with bacteria?" If Mr. Pearson had the slightest acquaintance with the subject he would know that this experiment has been tried over and over again, always with the result that the sterile "preparations" do not decompose.

We are not surprised to see that the author is his own publisher.

Pharmacology and Toxicology.

Materia Medica and Therapeutics. An Introduction to the Rational Treatment of Disease. Twelfth edition, revised. By J. Mitchell Bruce, C.V.O., M.D., F.R.C.P., Consulting Physician to Charing Cross Hospital; and Walter J. Dilling, M.B., Lecturer in Pharmacology, Liverpool University. London: Cassell and Co., Ltd. 1921. Pp. 678. 10*s.* 6*d.*

A book which has run through 12 new editions and a still larger number of reprints in 38 years has been judged by a higher criticism than can be given in any review. For such a long life the original material must be good, but so must also be the partial pyloric stenosis of the spasmodic or hypertrophic variety and urged operation.

Operation (June 9th, 1921).—Thorough exploration of the abdomen revealed no abnormality except a greatly dilated and moderately hypertrophied stomach, and a greatly thickened and widened pyloric ring over which the stomach was œdematous. This œdema extended for about two inches into the pyloric antrum. I could feel no ulcer in the duodenum, stomach, or pylorus. I was able to pass my index finger through the pylorus quite easily, after invaginating the anterior wall of the stomach. The second part of the duodenum was adherent to the liver and the adhesions tended to obstruct it. I mobilised the duodenum, separated the adhesions, and performed Finney's operation, enlarging the pylorus to 3 in. in diameter. The pyloric muscle was one-third of an inch thick and over half an inch wide. The mucous membrane showed a marked fold on the lower margin of the ring. Catgut was used throughout the operation.

It is now five months since the operation. The patient has not vomited since and has put on flesh to an amazing extent. He is entirely free from pain and thoroughly enjoys his food.

Remarks.

Partial stenosis due to spasm and hypertrophy of the pyloric sphincter was described many years ago by Mr. Ernest Maylard and others. Mr. Maylard has operated in about 35 instances; I have operated in about a dozen. In many cases, as in this one, there is a marked infolding and thickening of the submucous tissue at the pylorus, partly obstructing the channel, but there is no sign of active or healed ulceration. The diagnosis is difficult, for the patient is usually quite well and the stomach normal in the interval between the attacks, which, however, become more frequent, and ultimately dilatation of the stomach replaces moderate compensatory hypertrophy. Then, or during an attack, an X ray examination reveals dilatation and delay but no sign of ulceration. The clinical history is characteristic, the patient being well while at rest and under observation in hospital, and the attacks coming on after undue exertion or fatigue.

I suggest that some form of gastro-duodenostomy is the ideal treatment of this condition, for, unlike gastro-jejunostomy, this operation carries no risk of vicious circle or jejunal ulceration, and it does not materially change the normal anatomy and physiology of the stomach. I have generally adopted Finney's method of gastro-duodenostomy, by which the pyloric sphincter is divided and the pyloric opening greatly enlarged. My results have been uniformly satisfactory.

It has been suggested that this condition is a congenital abnormality—a persistence into adult life of a congenital hypertrophic stenosis, which is at first of such a moderate degree as to be compensated by hypertrophy of the stomach muscle; later this balance is upset and the stomach gradually fails and dilates. Would Ramstedt's operation, which has been so successful in infants, be suitable for this analogous condition in adults? I think not, for the fibrous changes in the pylorus—especially in advanced cases—call for the more radical operation.

Queen Anne-street, W.

LOSS OF REFLEX TO LIGHT RESTORED IN SLEEP.

BY A. GARVIE, M.D. GLASG.

THE interesting feature of the case here described is the restoration in sleep of a normal reflex after it had been absent during waking hours for over six days.

M. L., female, aged 14 years, was first seen March 21st, 1921. The mother stated that patient had been sick and vomiting on the previous day, and for the past 24 hours had been very sleepy. The child complained of frontal headache; temperature normal, pulse 80. Examination of nervous system revealed no abnormality. Odour of breath was slightly fruity and acetone was found in urine. No sugar or albumin present in urine. The child's previous history was good. She had suffered from scarlet fever the previous year.

On the 23rd a slight narrowing of the left palpebral fissure was noticed and lateral nystagmus. Pulse 67, erature normal. Slight retraction of muscles at back h legs. 24th: A paresis of the external rectus of left eye had developed, and the pupil appeared to be more sluggish to light reaction than the right. 26th: Patient was seen by Dr. G. W. Watson, of Leeds, and the possibilities of encephalitis lethargica or early tuberculous mischief were discussed. There was no evidence of any tuberculous process in any other region of the body, nor was any found up to time of death. 31st: Squint was now marked; there was some retraction of the head, and pupils were sluggish in their reaction to light.

On April 1st the patient was much more comfortable, pulse 70, temperature normal, and no acetone now present in urine. On the 8th the pupils were almost fully dilated with a very doubtful reaction to light. The paralyses of external recti were well marked. There was no headache and patient was very talkative but rational. From the 11th onwards she suffered from incontinence of urine. From the 1st to 23rd the pulse-rate had been gradually increasing to 120 per minute. Temperature had never exceeded 99° F. A little movement of the eyes could be elicited and there was a slight internal squint on right side. Pupils were almost fully dilated; there was no reaction to light and she could not see even a bright light. The frontal suture was slightly prominent and the temporal veins left side were more marked than on right. The fundi were still normal, except that on nasal side of left fundus the outline of the disc appeared to be slightly blurred.

25th: Patient was again seen by Dr. Watson, who made a detailed examination and corroborated these observations. 27th: Eyes were fixed in state of rest with pupils fully dilated. 29th: When seen about 10 P.M. patient was in a quiet sleep, and although one very rarely seeks to disturb a sleeping patient, I raised the eyelids and found that the pupils were contracted almost to the size of a pin-head, and on applying the light test I found that a normal brisk reflex was present in both eyes. As the result of applying the test the patient gradually awoke and one could observe the pupils dilating up in the process. Reaction was present until pupil was fully one-eighth inch diameter; greater than that diameter reflex was not present. As the observation was surprising I waited beside the patient for an hour and repeated the test twice as soon as it became evident that patient was sleeping again, and the same observations were made each time. 30th: There was considerable jerking of left leg. The patient was still partly conscious, but most of her conversation was limited to "Yes" and "No."

May 1st: There appeared to be some slight analgesia in second division of fifth nerve, right side. 2nd: Patient had been wakeful for two days, the mother stating that she had not slept for an hour. There was now analgesia in all areas of the fifth nerve, right side, and slight drooping of angle of mouth. There was some difficulty in swallowing and the child refused to take any solid food. When seen that night she had developed Cheyne-Stokes respiration, and she died early next morning.

During the course of the illness she was considerably troubled with constipation. I never found temperature to exceed 102° and the pulse remained rapid up to the end, being 160 on the evening preceding her death. During the illness there was said to be several slight convulsive attacks. I never saw her in one of these. A post-mortem examination was not obtained.

Remarks.

Since the brain is enclosed in the rigid cranium the volume of the blood in the cerebral vessels cannot alter unless the volume of the other cranial contents alters in the opposite sense. It appears to be a reasonable hypothesis to assume that in this case the blocking of the light reflex was due to a congestive disturbance leading to increased pressure on the third nerve. Halliburton writes:—

"Plethysmographic records from the arm of a sleeping man show a diminution in the volume of the blood every time he is disturbed, even though the disturbance may not be sufficient to awaken him. This is interpreted as meaning a diminution in the blood of the body and a corresponding increase in the blood flow through the brain."

This clinical observation seems to support the explanation placed on the plethysmographic observations: diminished volume relieving pressure when the child was asleep and gradual increase of volume as the child awakened increasing pressure on the nerve, paralysing it as manifested by the dilating pupil, and finally blocking the reflex.

Cases of this type are fortunately very rare in general practice, but it appears to be worth recording, for, if the explanation be physiological rather than pathological, it is likely to occur in the early stages of basal meningeal conditions, and may prove of value in investigating curative influence of sleep.

Halifax.

THE LANCET.

LONDON: SATURDAY, DECEMBER 31, 1921.

1921.

TIME was, and not so long ago, when we attempted in the last issue of the year to summarise its medical events; and long after such an annual résumé could be otherwise than capricious in character, we were informed by our readers that, within its limits, they found it of service. It supplied them with milestones along the road. But even this much can no longer be done by any compendium of medical history treating of the happenings of a year, and within the scope of a weekly newspaper's production. The fact that nothing approaching the old-fashioned "Annus Medicus," however deliberately restricted in circumference, can possibly represent the annual progress of medicine, is a practical testimony to the extent and range of that progress.

But this much can be said of the medical year just closed, and it is of great significance. While 1921 has been marked by no great discovery and by no fundamental change in professional organisation, all the medical activities of the year have revealed a general recognition of the unity of medicine in the largest sense. To insist upon this unity—to point out that the clinician, general and special, the pathologist, in mortuary or laboratory, the practitioner, at home or abroad, and working as individual or public servant, have a common object and interdependent aims—all this has been wont to form the text of introductory addresses and of writers on sociology. That much can now be taken for granted. Steadily, throughout the year just dead, the truth that medicine is one, one and undivided, though its practice be followed under such widely different conditions, has become patent to everyone. The necessity for close coöperation between clinical and laboratory work is seen to entail the necessity that facilities should be provided whereby practitioners should be able to obtain assistance in their common task from those who are able to give special advice. Departments there must be, but they should not be water-tight. On the contrary, the freest communication is required between them in order that the collated knowledge and experience represented by each and all may be at the disposal of a public which is to-day fully aware of the debt owed to our science.

◆

Renal Function Tests.

THE subject of renal function has assumed considerable importance in recent years, and much of the interest aroused is due to the labours of those biochemists who have devised simple yet accurate methods of blood and urine analysis. Not only have these methods proved of value in experimental investigations on animals, but the use of microchemical methods has enabled practically all of them to be applied to man. The advances made have shed a new light upon the subject of biochemical changes in health and disease. Although at the moment it cannot be said that the tests for renal function have approached the ideal, the fact that they have already been found of great value is proved by the eagerness with which both physician and surgeon seek help from them in diagnosis and prognosis of renal insufficiency. A group of American workers have attacked the problems with remarkable success; and the names of FOLIN, DENIS, VAN SLYKE, MYERS, ROWNTREE, GERAGHTY, FITZ, and FINE stand out prominently in this connexion. Many observations on experimental pathology have been made, especially by SCHLAYER, and his co-workers at Tübingen. From France comes the work of AMBARD crystallised in the laws and coefficient which bear his name. Our own country has also contributed valuable work to this particular branch of applied biochemistry. The potassium-iodide test was first devised by DUCKWORTH as far back as 1867. In more recent times D. CORBETT, MACKENZIE WALLIS, MACLEAN, and DE WESSELOW, among others, have placed certain renal function tests on a fairly firm and satisfactory basis. The simple and excellent urea-concentration test devised by MACLEAN and DE WESSELOW may be mentioned as of particular value.

To enumerate all the various tests which have been devised for determining kidney function would be unprofitable. Many of the tests have now become of historical interest only, whilst others which should be obsolete are employed by certain workers mainly on account of simplicity and perhaps through habit. The chief difficulty which has to be faced by a physician anxious to ascertain the exact nature of the pathological lesion in a kidney is the provision of a far larger amount of renal epithelium than is actually required for every-day needs, and thus renal function tests do not differentiate minute disturbances of function. The tests do, however, enable the physician to define the state of the kidneys in acute and chronic nephritis, functional albuminuria, arterio-sclerosis, uræmia, and myocardial degeneration, and are of particular value in the differentiation of cases of uræmia from cerebral hæmorrhage and other diseases which may simulate the former. In Prof. H. MACLEAN's recently published monograph,[1] intended and admirably adapted for the use of the general practitioner, he emphasises the value especially of the estimation of the blood-urea content, the urea-concentration test in the urine, and the diastase content of the urine, as simple tests which appear to give information of as much value to the physician in most cases as do more complicated ones. Dr. JOHN D. COMRIE has described in our columns[2] experiences with certain renal efficiency tests—viz., the phenol-sulphone-phthalein test, the urea-concentration test in the urine and the urea content of the blood, and concludes that these tests supply reliable information. He is in agreement with many American workers in placing most reliance on the phenol-sulphonephthalein test, both as regards reliability and also for its individual worth in diagnosis. This test has, however, not found general favour in this country. The investigation of "trench nephritis" gave opportunities for much valuable research to Dr. LANGDON BROWN, Dr. MACKENZIE WALLIS, Dr. ABERCROMBIE, and Prof. MACLEAN. The last carried out a most extensive investigation and elaborated a simple scheme of testing the renal efficiency of soldiers who had suffered from this disease. The value of this test is well known, and the collected data based on investigations of over 14,000 cases are sufficient to show its wide range of application. In the monograph previously referred to Prof. MACLEAN deliberately refrains from elaborate theoretical discussions accompanied by extensive surroundings. Prof. Hall referred to recent work on the permeability and penetrability of various organic and mineral acids, which supported his view that much would be gained by the application of pH determinations to body fluids such as gastric, pleuritic, ascitic, and urinary fluids. It seemed probable that delayed alimentary and other functions, as well as defective absorption of exudates, would prove in large part due to an alteration in permeability on the one hand and hydrogen-ion concentration on the other, and that further work might reveal some means whereby this latter could be influenced favourably.

[1] Modern Methods in the Diagnosis and Treatment of Renal Disease. By Hugh Maclean, M.D., D.Sc., Professor of Medicine, University of London, and Director of the Medical Clinic, St. Thomas's Hospital. London: Constable and Co. 1921. Pp. 102. 8s. 6d.

[2] THE LANCET, Dec. 3rd, p. 1150

Dr. H. H. CARLETON read a paper on a Physiological Conception of Prolonged Hysterical Conditions.

Reviews and Notices of Books.

HEART DISEASE AND PREGNANCY.

By Sir JAMES MACKENZIE, M.D., F.R.C.P., LL.D. Edin. and Aberd., F.R.S. Director of the Institute for Clinical Research, St. Andrews. London: Oxford Medical Publications. 1921. Pp. 138. 8s. 6*d*.

As Sir James Mackenzie rightly but severely remarks, advances in cardiology are not incorporated in books on midwifery, and many obstetric writers have not taken the trouble to familiarise themselves with modern views on this branch of medicine. Thus the text-book teaching of the treatment of pregnant women suffering from heart disease is sketchy and quite unhelpful. Some chapters of this monograph have already appeared in substance in our columns, and the whole gives a clear outline of a difficult subject.

After pointing out the normal sequence of events during pregnancy in the circulating mechanism, Sir James Mackenzie devotes successive chapters to the changes in the diseased heart during pregnancy, the physiology of the heart in relation to its efficiency, the law of heart failure and of heart murmurs, with special reference to prevalent misconceptions regarding the import of these signs. He then proceeds to discuss in detail the various forms of heart disease and their relationship to pregnancy and labour; this section includes also consideration of irregular action of the heart, auricular fibrillation, the neurotic heart, congenital defects, and finally the management of cases of pregnancy complicated with heart disease. Stress is laid upon the need for recognition of the earliest symptoms of heart disease—namely, breathlessness in effort and palpitation. The presence in mitral stenosis of a diastolic as well as of a presystolic murmur, accompanying enlargement of the heart and distress on effort, indicates, in the author's view, damage to the heart muscle, and he lays down the rule that if auricular fibrillation is present pregnancy should be forbidden. In cases of aortic regurgitation, when the heart is normal in size and response to effort is good, pregnancy may be allowed, but if the heart is enlarged and there is a water-hammer pulse, the organ is probably permanently impaired and bearing a child will cripple the patient severely, even if she gets over her confinement.

This book has been written with the definite aim of directing the attention of those who conduct labours to the newer cardiology: it should prove of the utmost value to them and to obstetric teachers.

HEREDITY.

Vorlesungen über allgemeine Konstitutions- und Vererbungslehre, für Studierende und Ärzte. By Dr. JULIUS BAUER. Berlin: Julius Springer. 1921. Pp. 186.

THIS is a series of 12 lectures, of which the first six deal with the principles of heredity and variation, with numerous examples illustrating individual variation, mutation, and Galton and Mendel's theories. These make somewhat laborious reading on account of the statistical and mathematical material introduced. In the seventh lecture is given a list of the diseases and abnormal conditions in man recognised to follow Mendelian heredity. They are arranged according as they appear to be dominants or recessives, and form a lengthy but interesting table. Later lectures are more clinical in character, and deal with such matters as the "individual ductless gland formula," and the types which result from failure in the perfect interaction of the various internal secretions. Thus descriptions of the hypopituitary and hypothyroid dwarfs, and of the hyperpituitary giants are given; also an account of Sigaud's classification of man into the respiratory, digestive, muscular, and cerebral types. Various other clinical classifications of human types are discussed and illustrated by photographs. The concluding lectures treat of racial and sociological matters. This is a compilation of lectures, each of which was probably of interest to those attending, but the book contains little new matter.

SURGERY OF PERIPHERAL NERVE INJURIES OF WARFARE.

By HARRY PLATT, M.S. Lond., F.R.C.S. Eng., Hon. Surgeon, Ancoats Hospital, Manchester. Bristol: John Wright and Sons. 1921. Pp. 49. 4*s*.

THIS little monograph is a reprint of the Hunterian lectures delivered by Mr. Platt at the Royal College of Surgeons of England, and thereafter printed in the *British Journal of Surgery* and abstracted in THE LANCET.[1] Surgeons had long been waiting for an authoritative and judicial review of the various operations designed for the repair of injured nerves, and Mr. Platt has made an excellent contribution to surgical knowledge which will tend to stabilise judgment and technique.

LABORATORY MANUAL IN GENERAL MICROBIOLOGY.

Second edition. Edited by WARD GILTNER. Prepared by the Laboratory of Bacteriology and Hygiene, Michigan Agricultural College. London: Chapman and Hall; New York: John Wiley and Sons. 1921. Pp. 472. 21*s*.

THE dominant notes of the book are its intensely practical character and its comprehensive subject-matter. Its existence illustrates the extent to which bacteriology is studied in a number of American schools as a separate and complete science and not—as is, unfortunately, usual in this country—as a medical subject, a mere branch of pathology. The book aims at covering the whole field of bacteriology, not equally but without undue emphasis on any one branch. The first 149 pages deal in a series of practical exercises with general morphological and cultural methods and include, in addition to the usual practical exercises on sterilisation, media preparation, routine cultivation and staining methods, exercises dealing with the special properties of yeasts, moulds, and the demonstration of bacteria under natural conditions. The second part of the volume deals with the physiology of micro-organisms in 67 pages, and in a series of well-thought-out exercises demonstrates the very numerous physiological properties of bacteria. This part of bacteriology is inadequately dealt with in most laboratory handbooks and constitutes a valuable section of this book. Applied microbiology is given only 125 pages, 74 of these being taken up by the bacteriology of air, water, sewage, soil, and the dairy, 4 by plant microbiology, and 47 by animal diseases and immunity. Much useful information is given in an appendix of 93 pages.

The subject of animal diseases and immunity is inadequately treated and the book would be useless as a manual for the medical student; for example, the bacteria of tuberculosis and diphtheria are not described. The sections on applied microbiology are the weakest in the book. There is no account of the bacteriology of food apart from dairy produce, and

Annotations.

"Ne quid nimis."

THE STUDY OF DEEP X RAY THERAPY.

MORE than a year ago Dr. Reginald Morton related[1] to the Section of Electro-Therapeutics of the Royal Society of Medicine his impressions of deep X ray therapy gained during a visit to the Frauenklinik at Erlangen. After a week's study of the methods there employed he came away with the conviction that the apparatus and technique constituted a real advance in radiology. Admittedly no new principle was involved, but a greater degree of penetration and intensity was attained at Erlangen than elsewhere, and the results already shown in cases of uterine carcinoma, apart from surgical intervention, were, to say the least, very encouraging. A latent period of scepticism was followed by an increasing rush to the scene of action, with the amusing result that the admission thereto has been strictly rationed. The *British Medical Journal* of Dec. 3rd recounted the difficulties of Dr. Nordentoft, of Copenhagen, in getting to Erlangen. The fact is, and we have it from Prof. Wintz himself, that the work of the radio-therapeutic department has been seriously embarrassed by the attention given to it. Prof. Wintz is desirous of restricting the visitation to a post-graduate course to be held in the early part of next year. Those who intend to take part in it should not only possess a competent knowledge of the German language, but they would be wise to master a book[2] written by Dr. F. Voltz when he was head of the experimental laboratory attached to the radio-therapeutic department at Erlangen. It is a complete exposition of our knowledge of the character of X rays, their chemical and physical properties, and of methods for measuring their wave-length, their penetrating power through various substances, and their quantity in arbitrary units. Not only are these matters described in great detail, with a wealth of numerical tables and diagrams, but the secondary phenomena attending the passage of a beam of X rays through matter are also fully dealt with. The scattering of the primary beam, the excitation of secondary radiation, and the selective absorption have each to be taken into account in an attempt at estimating what the intensity of radiation at any particular point may be.

Dr. Voltz states that the main object of his book is to provide data from which the radiologist may estimate dosage. The treatment adopted is rigidly physical; mathematical formulæ are freely distributed throughout its pages and make its study exhilarating if difficult. The experimental plan of the work actually forms the basis from which the quantitative methods of measurement used in the Erlangen clinic have sprung. It has been felt for many years by radiologists that the means at their disposal for the accurate measurement of doses were scanty. The electrical method described here, which is based upon the principle of the first inoto-quantimeter of Szillard, has been much developed by German physicists in the last few years, and it seems likely enough that this instrument, or some variation of it, will become extensively employed by radiologists. Its use alone will not give them all the information they want, but the fundamental principles upon which it is based will necessarily become better known, and medical men will become more familiar with physical quantities and expressions of which at present they are rather shy.

MAURITIUS.

MAURITIUS defaults from the standard of the sanitary reformer, despite the fact that the island has been a Crown colony for over 100 years. Such was the inevitable conclusion to be drawn from the graphic account given by Dr. Andrew Balfour to the Royal Society of Tropical Medicine and Hygiene of a recent visit to the island, undertaken at the instance of the Colonial Office and with the object of reporting on the sanitary conditions which had been seriously complained of by the Governor, Sir Hesketh Bell. Up to the middle of last century Mauritius appears to have been a peculiarly pleasant place to live in. Its scenery affords as much variety as can be hoped for in an island rather smaller than the county of Surrey; its climate is mild and equable, even delightful between May and December, and though periodically prolonged heavy rains and destructive hurricanes occur, the porous volcanic soil dries rapidly. But since 1854, when a visitation of cholera swept away 17,000 of the inhabitants, Mauritius has been under the scourge of disease. In 1865 the chance call of a ship at Port Louis from the malarious African coast introduced the *Anopheles costalis*, and the deforestation then in progress, to make room for the sugar cane, had undoubtedly prepared a way for the outbreak of malaria which decimated the island in 1867 and 1868; 31,800 of the population succumbed to this epidemic. Endemic malaria still claims 3000 to 4000 victims every year. Antimalarial measures on a large scale have been attempted, and in many parts of the island canalisation of streams has been carried out or begun as the result of Major Ronald Ross's survey and classic report in 1908. Unfortunately, however, his recommendations were only imperfectly put into effect, despite subsequent efforts by local health officers.

Dr. Balfour found pools in the streets arising from defects in the water pipes, from overflow wastage or drainage from pools in the vegetable gardens; he found stagnant water collecting in waste tins, graveyard urns, and hollow shells of the large edible snail. From all these sources larvæ of *A. costalis* were obtained. The irrigation of extensive sugar plantations, the overflows from unchannelled streams, the reed-grown banks of streams and rivers, and the marine swamps also afforded sufficient evidence of mosquito-breeding haunts to account for the general prevalence of endemic malaria. On the other hand, certain areas are free from the pest, as the result of proper canalisation and clearing of growth of river margins, and here streams are so shaded that the spread of a water weed inimical to mosquito larvæ is allowed full scope. Apart from malaria, the other principal causes of death in Mauritius are pulmonary tuberculosis, dysentery, bronchitis, and pneumonia. The death-rate of children under the age of 5 years in 1918 was over 300 per 1000 births. For the spread of dysentery and enteric fever the shallow wells, with every chance of contamination from the surface which form the water-supply in many parts of the island, are mainly responsible. Moreover, the insanitary conditions of the towns and the primitive methods used for the carriage and disposal of excreta, call for the most active measures of reform throughout the island. In the market places flies reign supreme; dogs have free run of the garbage and refuse heaps, the most elementary precautions being neglected. In the outskirts, pigs in large numbers roam at will, even wallowing in the open sewage pits through the broken-down barriers. It is not surprising, therefore, that among other intestinal disorders helminthic disease, especially ankylostomiasis, is common. Although the health report for 1918 states that a new leper colony was being erected a few miles out of Port Louis, the old leper hospital, condemned as long ago as 1878, was still in use on the outskirts of the town at the time of Dr. Balfour's recent visit. The sale and distribution of hand brooms made by the lepers is doubtless responsible for the spread of the disease, which, in Dr. Balfour's opinion, is more prevalent than is judgment which absorbs the new and discards the old, not only the old which is proved wrong, but that which has become unimportant. New subjects in this edition are accessory food factors, detoxicated vaccines, delayed chloroform poisoning; new drugs are benzyl benzoate and ethanesal; new sections include natural mineral waters and baths, invalid diet, and a short account of the Dangerous Drugs Act. These last sections are useful in a book which has become a concise encyclopædia of the subjects of pharmacology and therapeutics as they concern the student and the young practitioner.

---

[1] THE LANCET, 1921, i., 24, 37.

[2] Die Physikalischen und Technischen Grundlagen der Messung und Dosierung der Röntgenstrahlen. By Dr. Friedrich Voltz, Physikalischer Assistent der Strahlenabteilung der Universitäts-frauenklinik Munchen. Berlin: Urban und Schwarzenberg. 1921. Pp. 300. M.96.

One of the great difficulties in writing a book for the student on materia medica, pharmacology, and therapeutics is the fact that at the time when he learns pharmacology and materia medica he is only just beginning to be initiated into medicine, and since he has no knowledge of disease treatment means nothing to him. The authors provide 52 pages of introductory material, followed by about 400 pages on materia medica, wherein the drugs are described with enough pharmacology and therapeutics to ensure comprehension. In the third part, under the name of general therapeutics, organs and systems of the body are discussed, with the diseases of each and their treatment. A definite scheme runs through each chapter of this section, wherein physiology, pharmacology, pathological relations, spontaneous prevention and recovery, and finally therapeutics are dealt with in turn. This enables the reader either to work straight through each system of the body, or to pick out without difficulty the pharmacology or the therapeutics, ignoring the rest.

The fact that throughout the book the doses of the metric system are given before those of the imperial measures may seem a small point, but it goes some way to help us over the change we must face in the future. In the external preparations percentage is strictly adhered to; it will not be so difficult to introduce the metric system for ointments as for internal remedies, and a beginning may well be made in this section. Simple prescriptions in the metric system, such as that given on p. 51, are useful in this connexion. Altogether the work is excellent; few books contain so much useful information in similar space, and at such a reasonable price.

Taschenbuch der Ökonomischen u. Rationellen Rezeptur. By A. FRÖHLICH and R. WASICKY, of Vienna. Berlin and Vienna: Urban und Schwarzenberg. 1921. Pp. 215. M.30.

THE war has indeed left many scars. This small book for German and Austrian doctors is devoted to pointing out how drugs which are unprocurable or very expensive may be avoided. It is an emergency pharmacopœia, dealing not only with drugs, but even with the prices of pots and glasses. The book is essentially of local and temporary value, but nevertheless contains much useful information.

What to do in Cases of Poisoning. Twelfth edition. By WILLIAM MURRELL, M.D., F.R.C.P. Revised by P. HAMILL, M.D., F.R.C.P., Lecturer on Pharmacology and Therapeutics, St. Bartholomew's Hospital. London: H. K. Lewis and Co., Ltd. 1921. Pp. 273. 4*s.* 6*d.*

WE are glad that Dr. Hamill has not materially changed the type of Murrell's well-known little book. The title so well expresses the scope of the book and the size and contents are so suitable for its purpose that alterations of its general form could only be deplored. The changes which have been made have been chiefly abbreviations and the replacement of any irrelevant matter by an account of a few new poisons and notes on treatment. Dr. Hamill has shortened rather than lengthened the book, and has made it even more practical than it was. In view of the present peace, and in the hope that it may continue, he has not included symptoms and treatment of war poisonings. One might suggest that any proprietary preparations that are worth mentioning in the text are also worth recording in the index. Many of the patent preparations on p. 25 and the following pages may give rise to poisoning, and the fact that their composition is stated would be missed by the practitioner referring to the manual in a case of emergency.

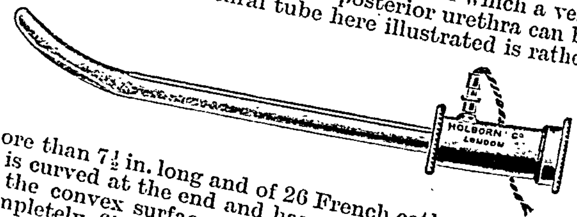
In a future edition it might be worth while to explain how the india-rubber bottle mentioned on p. 34 is used to fill the tube, and how iodide of starch (p. 37) is prepared. Though santonin poisoning may occur mainly in children, the use of the drug as a vermifuge is, we believe, equally common in adults. The obsolete tincture of jaborandi might disappear from p. 83, and the dose of diamorphine given on p. 139 is not strictly pharmacopœial. The symptoms of arsine poisoning are worthy of mention. They are different from symptoms caused by arsenic taken in other ways, while this form of poisoning is found to be commoner than had been previously thought, at any rate in industrial districts. But these are minor matters in a book so sound and practical.

The manual, written primarily for the doctor, is a safe and useful one in the hands of the nurse and of the layman; it may save life by giving the latter some hints how to act in emergencies, while it will not lead him to neglect to send for more skilled aid.

New Inventions.

A NEW URETHROSCOPE TUBE FOR THE POSTERIOR URETHRA.

I HAVE lately had made to fit the "Holborn" urethroscope a special tube by means of which a very clear view of the floor of the posterior urethra can be obtained. The urethral tube here illustrated is rather more than 7½ in. long and of 26 French catheter gauge. It is curved at the end and has an opening 1¼ in. long in the convex surface of the bend. This opening is completely filled by the pilot when introducing the tube, and I find it causes very little bleeding or discomfort to the patient. The tube is made to fit the body of the urethroscope, and lengthening pieces are supplied for the lamp holder and instruments to make up for the extra length of the posterior tube. The lens used is a large single one, ¾ in. in diameter, and does not require any adjusting or focussing, such as is necessary with more complicated and expensive instruments. The tube can also be used with the operating body, thus enabling the surgeon to carry out in the posterior urethra any necessary treatment as easily and with just as good an illumination as in the anterior urethra. It is advisable to give the patient a ¼ gr. belladonna suppository the night before and another an hour before the examination, and to wash out the bladder with oxycyanide of mercury afterwards. A local anæsthetic is rarely necessary. After the patient has passed water the tube is introduced as if it were a sound, and the pilot removed. The mucous membrane is then dried with mounted swabs and the body of the instrument attached. A little care and practice is necessary to prevent the window being pressed on to the mucous membrane. By gently withdrawing the tube and rocking from side to side, the walls and floor of the posterior urethra can be examined.



The instrument has been made for me by the Holborn Surgical Instrument Co., Thavies Inn, E.C.

Temp. Capt., R.A.M.C.
Military Hospital, Rochester Row.

from the medical student. The choice of Dr. R. H. A. Plimmer for the new chair of chemistry, attached to St. Thomas's Hospital in the University of London, is a happy one, and it will bring added strength to a school already well-equipped in the department of chemical pathology. It is still said with some measure of truth that the practitioner derives little benefit from a year at the preliminary sciences, because the materials and time at his disposal are so scanty that he can treat his patients only by the simpler clinical methods. The larger branch of medicine is still that founded on tradition modified by individual experience but untested by critical experiment, while the newer shoots grow only slowly at the expense of the old. Unless the practitioner is thoroughly grounded in the scientific bases of medicine he may fail to realise that biochemical methods do not exclude the older ones, but often serve to explain their action and justify their use. Prof. Plimmer's opportunity is to keep in touch throughout their career with students whom he has taught in their first year, and they will naturally return, even after qualification, to seek his help in the elucidation of problems.

PARATHYROID THERAPY.

MODERN views favour the complete structural and functional differentiation of the thyroid and parathyroid, though previously there was considerable doubt on the matter. Experimental work on the parathyroids has been largely confined to the production of tetany, and clinically this condition and other convulsive states have been studied in relation to these glands. From clinical and experimental work two functions have been assigned to the parathyroids; first, the control of calcium metabolism, and second, a function of rendering toxic substances harmless. In tetany Noel Paton and his co-workers showed that methyl-guanidine was the toxic causal agent of the condition of tetany and that this substance was normally destroyed by the parathyroids. Edmunds demonstrated that calcium in large doses would control the tetanic convulsions following parathyroidectomy. There does not seem to be any evidence that calcium plays a part in the detoxicating process in this condition. Launoy formulated a theory that infantile tetany was due to a preceding toxic state which damaged the parathyroids permanently, so that any subsequent toxic condition was liable to precipitate a tetanic attack.

In a recent communication to the Section of Therapeutics and Pharmacology of the Royal Society of Medicine Dr. H. W. Vines outlined these facts and proceeded to consider the effect of parathyroid therapy in cases where there is a calcium deficiency without any convulsive signs. His investigation was based on the fact that in a variety of conditions a deficiency is found in the ionised calcium of the blood, not necessarily accompanied by a deficiency of the total calcium. Over 100 cases had been studied by him, but in this paper he dealt only with ulcerative cases. These include 10 cases of varicose ulcer, 12 cases of gastric or duodenal ulcer, 2 cases of erosion of the cervix uteri, and 6 cases of inoperable carcinoma. Varicose ulcers were found to improve under intramuscular injection of calcium salts[1] up to a certain point, but did not proceed to complete cure; under parathyroid therapy[2] healing was more rapid in cases kept at rest and in early cases. For these ulcers g. 1/10 of the dried gland was given daily until laboratory tests showed that the ionised calcium had returned to a normal figure; the gland was then continued in reduced doses until healing was complete. According to Dr. Vines after-treatment is important; any irritation or eczema, premonitory of a return of the ulcer, must be met with an increase in parathyroid dosage, and thus the ulcer can be kept healed. Beneficial results were also obtained by parathyroid therapy in the cases of intestinal ulceration. Pain and vomiting were decreased, an improvement in the general condition was noticed, and weight usually increased. The disappearance of symptoms again appears to be consequent on the return of the ionised calcium of the serum to normal. Dr. Vines suggests that the important factors in these ulcerative conditions are a primary toxæmia combined with a secondary deficiency of ionic calcium. The latter may be due to the toxic effect of the former upon the parathyroid glands, disturbing calcium metabolism, the site of development of the ulcers being due to this general cause in conjunction with local causes. In varicose ulceration the latter local condition may be dependent on inadequate blood-supply, and probably some slight trauma in the varicose area where nutrition and cell resistance are least effective. In gastric ulcer there is the same general cause, and Dr. Vines has noted that gastric ulceration is commonly associated with some toxic state.

Friedman has shown that parathyroidectomised rabbits frequently developed acute gastric ulcer which did not heal spontaneously, whereas ulcers produced in healthy animals by mechanical means are said to heal invariably. Dr. Vines suggests, further, that in the former animals the absence of healing is due to a deficiency of ionic calcium following the removal of the parathyroids, but that in the latter animals calcium metabolism is normal and natural healing occurs. Dr. Vines claims that the results obtained by parathyroid therapy in these cases substantiate theories put forward by other workers; that there is evidence of the importance of ionised calcium in the repair of the ulcerated areas; and finally, that the beneficial effects obtained by him suggest that these ulcerative states are partially due to an insufficiency of parathyroid secretion. No marked changes have been observed in the condition of the carcinoma cases beyond a decrease in pain and discomfort during parathyroid treatment. In these cases Dr. Vines considers the ionic calcium deficiency as probably secondary to the malignant ulceration rather than primary. He concludes that the two factors common to all the cases are a chronic toxæmic state and a deficiency in the ionised calcium. He adds a speculative hypothesis that all acute or chronic toxic states may react harmfully to a greater or less extent upon the parathyroid glands, causing a disturbance in calcium metabolism and a decrease in tissue resistance. This is to some extent borne out by Thompson and Leighton's work, where induced and chronic parathyroid deficiency was manifested by loss of weight and greatly decreased resistance to infection. It seems possible that parathyroid therapy may be of use in certain chronic conditions, if not also during the acute attack of the more common infective ailments.

THE TREATMENT OF FRACTURES.

ABOUT five years ago Mr. E. W. Hey Groves presented a modest exposition of the therapeutics of fractures in which special operative methods and novel modes of fixation of bones, founded upon a long series of careful experimental observations on animals, were given the pride of place. For various reasons this monograph did not make a universal appeal; the armamentarium necessary for carrying out the author's original technical manœuvres appeared unduly formidable and complex, not only to the ordinary surgeon, but also to the surgeon possessing the true sense of bodily mechanics—an attribute appertaining to physiology rather than to carpentry. But in a second edition, which is to be regarded essentially as a new work,[1] the author has given the surgical world a monograph of rare judgment and bibliographies; but his assurance that he has included only those tests found after trial on a large scale to be of practical clinical value and to be easily carried out can be accepted without question. Incidentally, his views on the dietetic treatment of nephritis alone, adequately summarised in one chapter, deserve careful study. Practitioners will be interested in the unexplained but decided relief from dropsical symptoms in certain cases of parenchymatous nephritis when placed on a high protein diet, a phenomenon first observed by Epstein, and substantiated by Prof. Maclean; the oral administration of urea has also been found of value in selected cases. On the importance of ascertaining the state of the kidneys in certain surgical conditions Prof. Maclean has also some wise words to say.

[1] On Modern Methods of Treating Fractures, including the Jacksonian Prize Essay on Bone Grafting. Second edition. By E. W. Hey Groves, M.S., M.D., B.Sc. Lond., F.R.C.S. Eng., Surgeon to the Bristol General Hospital, Surgical Director of the Ministry of Pensions Hospital, Bath. Bristol: John Wright and Sons, Ltd. 1921. With 296 illustrations. Pp. 135. 30s.

As to the utility of renal function tests in surgical conditions they were originally introduced for the special purpose of helping the surgeon and they are also of importance to the surgeon in assessing operative risks. The latest discussion[3] which took place in the Section of Urology of the Royal Society of Medicine was confined to the surgical aspect of these tests; surgeons and pathologists spoke of the results they had obtained in the application of certain tests to cases of prostatitis, and unilateral and bilateral disease of the kidneys. The general consensus of opinion was that renal function tests were of value in cases of prostatitis, where there was no definite clinical evidence of renal insufficiency, but when the surgeon was doubtful whether prostatectomy should be carried out in one stage or by the two-stage operation. In cases where there was clinical evidence of considerable renal damage, the tests could be used to confirm the findings, and if positive the surgeon would refrain from operative interference. The chief tests used by most of the speakers were the urea content of the blood and the urea-concentration test. For genito-urinary diseases, associated with obstruction in the lower part of the urinary tract, the tests of choice appeared from the discussion to be those advocated by Prof. Maclean—the urea content of the blood, the urea-concentration test of the urine, and the urinary diastase content. In unilateral or bilateral diseases of the kidney ureteral catheterisation was generally advocated, combined with these tests. For convenience and rapidity the indigo-carmine test appeared to be in favour with some surgeons. The discussion clearly emphasised the necessity of careful clinical investigation of every case, and the importance of coöperation between the clinician and the pathologist. Renal function tests by themselves will not answer the question when to operate and when not to operate; neither can they predict the onset of an ascending infection of the kidneys. For the present, at least, the tests should be assessed by one who has had experience in their application and interpretation. But we reiterate here the hope, expressed in reviewing a little French book entitled "Comment interpréter en clinique les réponses du laboratoire?," that improvements in medical education will soon make such limitation obsolete.

◆

The General Practitioner and Public Health.

THE relationship between the public health services and the general practitioner has of late years become the subject of much consideration. The general practitioner must always be the executive officer in any scheme of medicine; in the first annual medica report of the Chief Medical Officer of the Ministry of Health, Sir George Newman made it clear that the practitioner should be not so much an agent for the treatment of obvious disease as an agent for discovery and arrest of disease in its early stages, and a missionary of personal hygiene in its preventive aspect.

A recent contribution to the subject was made by Dr. C. E. S. Flemming, a member of the Consultative Council of Medical and Allied Services, in an address delivered at Winsley before the West of England Branch of the Society of Medical Officers of Health. Nothing, said Dr. Flemming, has more hindered the development of the medical services than the want of association of the various sections of medicine—a want resulting partly from the individuality of the medical practitioner, but partly also from the prevailing lack of appreciation of the fact that the interest of the individual is also the interest of the community. When public health authorities undertook not only supervision of drainage, water-supply, and housing, but also notification, isolation, and treatment of cases of infectious diseases, their officers came into close contact with the family doctor, and friction sometimes resulted when part-time medical officers combined private practice with official work; but both sides now realise their interdependence. Apart from administration, it is hard to say where separate spheres begin for preventive and curative medicine. If a public health service is to be truly preventive it must consider and possibly control the environment of the people at home and at work, together with their food-supply and all preventable conditions which cause disability, besides participating in constant research. Dr. Flemming pointed out that every doctor in this sense must be a member of the public health service, and no official could ever have the same intimate knowledge of the patient's life-history, the same opportunity of detecting disease in its earliest stage, as the practitioner possesses. A communal clinic would be the place where the general practitioner and the medical officer could meet; at such a clinic the patient would require not only expert special opinion, but expert general opinion, and if the communal clinic were run on practical lines the practitioner's value to the community would be much enhanced. He should be able to follow up those cases with which he could not properly deal in his consulting-room or in the patient's home—follow them through to clinic or hospital. There are general difficulties of organisation, as well as many difficulties of detail, to be surmounted before the alliance of practitioner, specialist, and administrator can be made complete. Every student of the Dawson Report knows this. The practitioner is rightly jealous of his professional independence, and in indiscriminate consultation there lies a danger of loss of individual responsibility, as Dr. Flemming points out; but with his conclusion that the complexity of society renders necessary an intimate and hearty coöperation between all departments of medicine everyone will agree.

No point made by Dr. Flemming calls for more attention than his insistence upon the necessity for the following-up of patients by the medical practitioner who, with a knowledge of the personal and family histories, sends them to clinics or to hospitals, too often to lose sight of them entirely. In this way evidence of late results of treatment is lost—evidence which would, if collected and collated, be of the utmost value in the establishment and regulation of many treatments which now form the subjects of discussion. In several American hospitals, and at the London Hospital, experiments in some such direction as we have outlined have been successful, and it is clear that in following-up lies a development of the work of a practitioner most vital for the advancement of public health.

---

[3] THE LANCET, Dec. 3rd, p. 1161.

for the moment the possibility of some of these cases having had concealed tuberculous lesions which responded to the tuberculin, this treatment recalls the attempt to treat the sensitised patient with heterogeneous protein, as in the therapeutic application of tuberculin. Prof. van Leeuwen has not followed out this line of thought as far as he doubtless will in the future if his results should be confirmed by himself and others; but in the meanwhile we record it as another effort to explore protein sensitisation, a condition which looms in the background of many obscure pathological conditions.

HÆMATOPHAGY.

IT is generally agreed that "old" red blood corpuscles are normally taken up in small numbers by phagocytic cells in the spleen and bone-marrow. Under pathological conditions abundant phagocytosis may be found in these situations, in lymphatic glands, and occasionally in the circulating blood, the active cells being endothelial and large mononuclear leucocytes. This view appears to be firmly based on objective facts. The further history of these eaten red cells is not so clear, though a quantity of evidence of various kinds is consistent with the received idea that they are broken up by some process akin to digestion, and the remnants used to form fresh red cells in the bone-marrow, except for that part of the hæmoglobin which is diverted as bile-pigment to the bowel. Dr. H. M. Woodcock, well-known for his varied work in protozoology, has lately[1] proposed that this process of hæmatophagy, as he calls it, is of more frequent occurrence in the body than has been supposed and of far wider significance. His work began with a study of the nature and origin of blood-platelets, and he concludes that these bodies represent certain products of the digestion of red blood corpuscles in the cytoplasm of large mononuclear cells and megacaryocytes, together with a small portion of the cytoplasm itself, separated from the cell. His derivation of platelets from the giant cells of bone-marrow is in accordance with the work of J. H. Wright, and several writers have affirmed a belief in their origin from red corpuscles; Dr. Woodcock combines these apparently divergent views in an original conception. He suggests, further, that the enigmatical round areas found in the cytoplasm of the guinea-pig's leucocytes ("Kurloff bodies"), which have been variously interpreted as parasites, secretory products, and archoplasm, are in reality red corpuscles in process of digestion along somewhat abnormal lines. The same interpretation is then applied to the Negri bodies found in the brain in rabies, and to the Guarnieri corpuscles in the epidermis in small-pox and vaccinia. And finally, the small stainable objects found inside endothelial cells in typhus, and recently identified as the causative parasite *Rickettsia*, are explained as being nothing more than platelet granules, a by-product of the digestion of red corpuscles. It looks indeed almost as if Dr. Woodcock would soon be advocating that a good many of the tissues of the body feed upon the red corpuscles in gross, and out of them make at least a sensible proportion of the curious appearances on which the histologist whets his imagination. Some such extension of the import of hæmatophagy is, in fact, hinted at towards the end of his paper.

New interpretations of old phenomena are always of interest, and the unconventional conclusions of one who comes without prejudice and with a wealth of microscopical experience into well-trodden paths that he has not explored before are sure to be worth consideration. But it seems scarcely probable that Dr. Woodcock will convince on his present evidence. His conclusions are based entirely on the similarities of microscopic appearances, using rather a limited range of methods of preparation. The tracing of sequences and developments in this way is notoriously liable to error, and in his own sequences the early stages of the transformation at which the body under examination is indisputably a red corpuscle, and yet not an unaltered one, seem to be sparsely illustrated. He has, however, the immense advantage over others in that he has been able to ponder over the actual specimens, for which the best drawings must be a poor substitute, though Miss Rhodes's pictures, accompanying Dr. Woodcock's contribution are very good. As in all such cases, one must attach more weight to the author's interpretations than one would readily do were his data capable of complete presentation to the critic. The nature of blood-platelets, of the bodies of Kurloff, Negri, and Guarnieri, and of the admittedly doubtful *Rickettsia*, are not certainly known. There does not appear to be anything in Dr. Woodcock's theses concerning them which is flatly at variance with agreed facts. More cannot yet be said, for experiment is lacking.

EPITROCHLEAR ADENOPATHY IN SYPHILIS.

ACCORDING to Dr. R. H. Rulison,[1] the importance of enlargement of the epitrochlear glands as a diagnostic sign of syphilis was first described by Sigmund and was later emphasised by Fournier, De Amicis, Hochsinger, Heubner, and others. Dr. Rulison's own observations were made on 252 cases of syphilis and 43 non-syphilitic cases at the Department of Syphilology of the Bellevue Hospital, New York, with the following results: (1) Epitrochlear adenopathy was found to be an early, persistent, and common sign of syphilitic infection, being present on one or both sides in 79 per cent. and absent in 21 per cent. (2) It was not pathognomonic, for it was found in 23·25 per cent. of the non-syphilitic cases. (3) It proved to be a valuable aid in diagnosis during a period of the primary stage, when both the dark-field examination and the Wassermann reaction were often negative. (4) It was valuable in treated and latent cases, and when present called for repeated laboratory tests before the possibility of syphilis could be excluded. (5) Since the condition was unilateral in one-tenth of the cases of syphilis, the statement that unilateral adenopathy is non-specific is unwarranted, and cases presenting this condition should be investigated with the same care as those with bilateral adenopathy. (6) Treatment did not cause complete resolution of the adenopathy. (7) Epitrochlear adenopathy was less common in neurosyphilis than in other forms of the disease.

THE MEDICAL INSURANCE AGENCY.

A MEETING of the Committee of Management of the Medical Insurance Agency was held at 429, Strand, on Friday, Dec. 9th, when the Chairman, as a preliminary, introduced to the Committee Mr. L. FERRIS-SCOTT, F.C.A., who has recently succeeded Mr. W. E. Warne as financial secretary and business manager of the British Medical Association. Mr. Ferris-Scott is acting as secretary or general supervisor of the financial side of the Agency.

Chairman's Interim Report.

Dr. G. E. HASLIP, the chairman, made an interim report to the Committee covering nine months ending Sept. 30th, 1921, and was able to show that all the business transacted by the Agency showed steady progress. He said:—

> Life assurances and insurances of motor car risks, which are two of the principal sources of income to the Agency, continue to increase, reflecting the confidence placed by members of the profession in the advice and assistance given by the Agency in the completion of suitable contracts. In life business, the Agency has maintained the high standard set up in 1920 in the number of new policies negotiated. The contracts have been spread over a group of offices of the highest standing, thus continuing the principle of combining security for the assured with complete freedom of action for the Agency.

generally recognised. The want of proper supervision of vessels moored to the quayside of Port Louis readily admits of the transmission and spread of plague by infected rats which are able to land without restraint.

It is evident from Dr. Balfour's disclosures that drastic action is imperative. To meet the situation, a levy on the sugar industry, the staple trade of the island, to the amount of £1,000,000 has been proposed. But more than this is called for. Inadequate medical and sanitary staff with insufficient authority and power of administration would seem to account for much of the delay in carrying out the greatly needed preventive and sanitary measures of reform. Much good work has been and is being done by the Mauritian doctors in the hospitals, bacteriological and public health departments, but their powers are limited and their range of duties overwhelming in the face of such heavy odds. Valuable aid has been rendered by voluntary bodies and by the Rockefeller Foundation. Dr. Balfour is hopeful that the unenviable reputation of the island may yet be removed by the application of modern knowledge on vigorous and sound lines. But the efforts will have to be persistent and strenuous, and, moreover, inevitably expensive. The picture of the insanitary conditions of the island drawn by so impartial an observer as Dr. Balfour does not appear to fix the responsibility therefor on any one race, but would imply that the community as a whole pays but little attention to the counsel of its medical advisers. Dr. C. L. D'Avoine, whose letter we publish in this issue, appears to blame the slackness of the supervision exercised over the coolie class which, in view of Dr. Balfour's exposure of the general attitude, is hardly surprising.

THE GENESIS OF TUBERCULOUS DISEASE.

ONE of the most remarkable tendencies in modern medicine is to refer the genesis of disease in adult life and old age to childhood and even to infancy. Mental disease in the adult is now often traced to psychic trauma in childhood, and the monarticular arthritis of middle and old age to almost forgotten and apparently transient injuries to the same joint several decades earlier. Many similar examples could be given. In the past we have been rather like the child who, seeing a picture of an iceberg, thinks that it is floating on the surface of the water, and does not appreciate the size of the mass of which only a small fraction is visible. The discovery of the tubercle bacillus gave us for many years a myopic view of the duration of that disease. Inoculation of animals with the tubercle bacillus being followed in a few weeks or months by fatal tuberculosis, what was more natural than to assume that some similarly expeditious process was that which usually occurred in man? There was, indeed, much reliable evidence to prove that a rapid sequence of infection, disease, and death is fairly common. For many years Behring's dictum that pulmonary tuberculosis in the adult is the end of the song sung to the baby in his cradle was regarded as more poetic than true. In 1895 Dr. K. F. Andvord, of Christiania, put speculative hypothesis on a much surer footing, and a perusal of his statistical and critically analytical paper[1] leaves even the modern reader impressed by his insight. Many of the criteria by which the hypothesis can now be tested were then lacking; the Pirquet test, for example, had not been devised. Yet Dr. Andvord found enough evidence on which to make out a plausible case, and the mass of papers which have appeared on this subject since 1895 are a bulky testimonial to Dr. Andvord's pioneer work.

In the current number of *Tubercle* Dr. Andvord discusses the relation of tuberculosis in the adult to infection in childhood, and shows how the evidence of post-mortem examinations, of mass clinical examinations in certain areas, of vital statistics, and of many other lines of investigation can be made to converge on this one point. One of the tests to which he puts his theory is the consideration of the influence of a vigorous anti-tuberculosis campaign on a population classed in so many age-groups. If his theory is correct, this campaign should first reduce the incidence of tuberculosis in the youngest age-class, and should for many years have little or no influence on the older classes. For persons over 30, for example, would have received their fatal infection much earlier. The experience of the Finnish National Association for Combating Tuberculosis throws instructive light on this point. In 1909 a certain district in Finland was selected for a large-scale experiment in anti-tuberculosis warfare. A mass clinical examination of practically all its inhabitants was made, and then for 10 years a hustling anti-tuberculosis campaign was conducted, with a network of dispensaries, propaganda centres, and many other weapons. At the end of this period another mass clinical examination was conducted in the same district, and it was found that the cases of pulmonary tuberculosis had dwindled to a third of their total number 10 years ago. But while, in the first decade of life, this morbidity was less than a quarter of what it was, the reduction in the second decade of life was only to a little less than a third, and in the third decade only to a half. Between the ages of 30 and 50 there was little or no change in the morbidity from pulmonary tuberculosis. Another conclusion to which Dr. Andvord comes is that not only is the fatal pulmonary tuberculosis of adult life the result of severe infection in childhood, but that in a large proportion of cases the disease is clinically demonstrable from childhood onwards. Even in childhood it is possible to distinguish between the case showing a mild, benign infection, and that already more or less doomed to develop fatal tuberculosis later in life. Dr. Andvord, indeed, goes so far as to say that the gulf between the two is wide. He admits the possibility of a narrow belt of intermediate cases running between these two extremes, but maintains that it is very narrow.

If, as he argues, 80 to 90 per cent. of fatal cases of pulmonary tuberculosis begin within the first three or four years of life, and if by deferring the first infection till after the fourth year we can force it to assume a permanently benign instead of a slowly virulent character, the task of suppressing tuberculosis is greatly simplified—on paper at any rate. We may, perhaps, come to focus attention on these first four fateful years instead of frittering away our energies and resources in rescuing from exposure to infection adults who are either already more or less immune on account of a benign, accidental inoculation, or whose real danger lies in a series of reauto-infections. This class requires rescuing on quite other principles than the prevention of exogenous infection. The time may not be far distant when almost every potential consumptive will be identified as such in early childhood, and will enjoy systematic supervision and treatment to the end of his days so that he may not end them in the misery of fatal pulmonary tuberculosis. The comprehensiveness and simplicity of Dr. Andvord's conception of tuberculosis are certainly alluringly plausible.

THE THREAD OF BIOCHEMISTRY.

WHETHER the medical student should be taught chemistry, physics, and biology as independent sciences, or go through a specially selected course in consideration of his future needs, is still a moot question. Presumably within a few years a preliminary survey of these subjects will have been made by every student during school years, specialised courses being reserved for the medical curriculum. In any case a considerable extension of biochemical teaching may be forecasted, for the proper interpretation of many of the newer clinical methods of investigation—for example, gastric analysis, determination of basal metabolism, calculation of diabetic diets, and renal function—depends on a knowledge of biological chemistry greater than that now exacted that the average consumer judges his milk-supply. *It is also of the greatest importance to the dealer.* In order that the condition of the milk at all periods of the year, and at varying ages might be known, samples have been studied week by week since November, 1916.

---

[1] Norsk Magazin for Lægevidenskaben, 1895, No. 12.

Bacteriological Condition.

From November, 1916, to December, 1918, clean milk was examined when 24 hours old, and during that time it failed to pass the highest standard of bacteriological cleanliness (10,000 colonies in 1 c.cm.) on three occasions only. On two of these occasions the bacteriological counts did not exceed 230,000, and coliform organisms were not found in 1 c.cm. of the milk. On the third the number of colonies of bacteria was uncountable, and coliform organisms were found in 1 c.cm. of the milk. This was the only really unsatisfactory sample which was received among 100 samples examined during a period of more than two years. On ten occasions coliform organisms, as represented by the production of acid and gas in lactose-peptone water, were found in 1 c.cm. or less of the milk.[3]

When these results were compared with those obtained from the samples of average milk, generally not more than nine and never more than 12 hours old at the time of examination, a great difference in bacteriological cleanliness was found. Whereas the clean milk maintained an almost uniform standard, which was well below the 10,000 limit at all seasons of the year, the average milk could not be relied upon to maintain any bacteriological standard from one day to the next. Sometimes two or three consecutive satisfactory counts were found and then they would run up, perhaps into the millions, and remain there throughout a prolonged series of examinations. There was no sort of uniformity in the counts obtained, and 65 of the 96 samples which were examined contained coliform organisms in 1 c.cm. or less.

The difference between the two sets of results was extremely interesting, especially when it is remembered that the clean milk was 24 hours old at the time of its examination, was cooled at the farm, with water from a deep well, to temperatures which varied by as much as 16° F. (46° F. to 62° F.) in the course of a year and travelled by rail in pint bottles without any special provision for keeping it cold, so that it reached the laboratory at temperatures which varied between 37° F. and 76° F. The average milk on the other hand was not more than 12 hours old when examined.

Relative Periods of Sweetness.

When a study was made of the relative periods of time during which the samples from these two sources remained sweet under similar conditions of storage in the laboratory, it was found that there was a marked difference in the keeping qualities of the two types of milk. This is demonstrated by the figures shown in Table II.[3]

TABLE II.

Milk.	Period.	Total no. of samples.	No. sweet for more than 1·75 days at lab. temp.	No. sweet for less than 1·75 days at lab. temp.
Clean ..	31/5/17 to 31/5/18	51	51	0
Average	31/5/17 to 30/5/18	49	24	25

Table I. shows that no sample of clean milk was sour within a day and three-quarters from the time of milking, whereas 25 of the 49 samples of average milk were sour within this period of time. It is difficult to over-estimate the economic importance of this observation since a successful milk trader must be in a position to guarantee sweetness in the consumer's house.

Influence of Worker and Farm Conditions.

The study of the causes which gave rise to these different types of milk naturally followed on these results, and the nature of that study was to some extent influenced by the conditions which existed on the farm which was producing the clean milk which has been described. The milk on that farm[4] was being taken in a special milking-shed, and into covered buckets by clean milkers, who had the advantages of an abundant water-supply and light. After it had been taken from the cows it was carried to a specially constructed dairy in which it was cooled and in which all the apparatus necessary for washing and steaming utensils, &c., was provided. The buildings involved a considerable capital outlay which was hardly possible to many farmers. It was, therefore, necessary to discover by what means and to what extent similar results could be obtained in an ordinary cowshed.

This work was done by Knight and Freear[5] and the results were published in 1920. It was carried out in an ordinary cowshed, and the milking was done at the same time as that of the cows which were not being used for the experiment. The success of the experiment did not depend upon any special advantages in the surroundings in which it was performed. Table III. shows the results which were obtained and demonstrates the possibility of producing clean milk under average farm conditions, provided that the milker understands his business and is provided with light, water, and steam.

TABLE III.

(A) Numbers of samples showing more than 10,000 colonies in 1 c.cm. of milk.

(B) Average of colonies found in 1 c.cm. of milk in remaining samples.

Series.	Date 1918–1919.	—	No. of expmnts.	Buckets.	(A)	(B)
1	Oct. 12th to Nov. 13th.	Buckets washed by farm hands.	12	O.	2	2360
				C.	10	10000
2	Nov. 13th to Dec. 11th.	Buckets washed by clean milker (farm method).	14	O.	1	3200
				C.	2	3991
3	Jan. 11th to Mar. 3rd.	Buckets washed and steamed, cows ungroomed.	30	O.	5	4274
				C.	0	1505
4	Mar. 5th to June 20th.	Buckets washed and steamed. Cows' udders clipped.	51	O.	10	2505
				C.	2	516
5	June 23rd to Sept. 4th.	Buckets washed and steamed. Udders clipped, cows washed and dried.	42	O.	2	900
				C.	2	388

O., open. C., covered.

These experiments were conducted over a limited period of time at a particular farm, and although since repeated with similar results under conditions worse than those existing at this farm, yet it remains to be shown whether it is possible to produce really clean milk in a cowshed with the same certainty as when the milk is taken in a special milking shed. That problem has yet to be investigated. It is, however, quite clear that, given the right person, with comparatively little apparatus very wonderful results can be obtained in an ordinary cowshed. The chief factor in the whole situation is the individual.

Influence of State of Utensils.

While this work was in progress evidence had accumulated which led us to think that the condition of the utensils had an important bearing upon the cleanliness of the milk. Attention was first drawn to this fact by the consideration of the results obtained from the average milk in the first series of experiments which have been described. When the results were set out in a chart it was found that there was an astonishing rise in the bacterial content of the milk during the months of May to September in each year. The milk was being examined at a maximum age of maturity. His enthusiasm for some of the technical procedures which he himself has introduced remains undiminished, although he writes modestly enough of his results. His method of using an encircling suture in fractures of the patella—far more efficient than the conventional operation—should now be established as a routine. Mr. Hey Groves's views on bone grafting are particularly illuminating, especially his exposition of the indications for using the inlay bone graft and the intramedullary bone graft. The influence of his wide experience, derived from a participation in the reconstructive surgery of the war during the past five years, can now be traced in the critical survey which he has made of the whole gamut of fracture therapeutics. Mr. Hey Groves leads us step by step to see that the modern treatment of fractures implies the application of an appropriate procedure to a given type of fracture or at a certain stage in any fracture: there is no real conflict between the schools representing, for instance, the non-operative and the operative methods of treatment. The modern fracture surgeon must be a master of all methods, and must know when and where to apply any particular one. The thesis is developed and maintained in a most lucid and convincing manner, and will serve as a model for sections on fractures in future text-books of surgery.

TREATMENT OF SYPHILIS IN THE NAVY.

THE results of treatment for syphilis are more patent in the Navy than elsewhere, in so far as the patients are continuously under medical control and rarely pass out of sight. Two articles[1] by Surgeon-Commander Laurence Kilroy, on the treatment of syphilis in the Mediterranean Fleet, are the more welcome as the Fleet Medical Officer is not responsible for any single ship, but is advisory to the whole staff of medical officers. Commander Kilroy measures the success of treatment by its effect on the Wassermann reaction, though he hopes that the quicker Sigma test (THE LANCET, 1921, i., 956) may replace that. He finds that intramuscular injections of arsenobenzol once a fortnight produce more effect than intravenous injections at shorter intervals, and that courses of mercury by the mouth increase the effect of arsenobenzol on the W.R. He distinguishes five classes of cases of syphilis, with appropriate treatment for each.

A. Early primary: In the first fortnight after the appearance of the sore, spirochæta pallida seen with dark-ground illumination, W.R.−. *B*. Late primary: Sore, and W.R.+. *C*. Secondary: Usual signs, and W.R.+. *D*. Old cases: W.R.+, and perhaps other signs. *E*. Old cases with nervous symptoms or positive Wassermann in cerebro-spinal fluid.

An *A* case gets a "unit course," that is in four months, eight intramuscular injections of NAB, or sulpharsenol, at fortnightly intervals, and at the same time 4 gr. of grey powder daily. If at the end of the course there are no signs of syphilis and W.R.−, treatment ceases; but the serum is tested every three months for two years, and if on all these eight occasions W.R.− patient is considered cured. If a W.R.+ appears at any time, patient has become a *B* case and is treated accordingly. A *B* case or a *C* case gets a "unit course," then three months' mercury by the mouth or by injection, followed by a second unit course, itself preceded and followed by a W.R. If both tests are negative, treatment ceases and W.R. is tested every three months for two years. If all are negative, patient is considered cured. If the preceding W.R. is positive, but the second negative, repeat the unit course after three months' mercury, with a W.R. before and after. A W.R.+ at any time after the second unit course makes the case a *D* case. All *D* cases should have their cerebro-spinal fluid completely examined in hospital: a W.R.+ makes the case an *E* case. If the cerebro-spinal fluid of a *D* case gives a W.R.−, send patient back to his ship, give him three unit courses, with mercury in the intervals, testing the W.R. before and after the second and third courses. If no, two consecutive W.R.'s are negative, give "half unit" (four injections) every four months, the reaction being tested before and after. As soon as two consecutive W.R.'s are negative stop treatment and merely test the reaction every three months for two years, and if all are negative consider patient cured. A W.R.+ now at any time makes patient an *E* case, to be treated in hospital by a specialist.

Commander Kilroy considers the appointment of consultants in syphilis to be a great advance, but he holds that ordinary cases of syphilis up to *E* may be treated on board; they do not require to be sent to hospitals. In hospital they cost 15*s*. 6*d*. per day (pay 5*s*. 6*d*., hospital charges 10*s*.); in ships they cost 7*s*. 6*d*. per day (pay 5*s*. 6*d*., victualling 2*s*.), and the service avoids the trouble and time spent on transferring them. Appeal is made for a specialist at headquarters to coördinate the work of the specialists in syphilis throughout the service, and to advise what methods have been found most satisfactory. Those concerned with the treatment of syphilis will find it well to study Commander Kilroy's papers. Out of a total number of 46 cases in *Iron Duke*, all *A* and *B* cases recovered, 83 per cent. of *C*, and 64 per cent. of *D*.

ANTI-ANAPHYLAXIS.

THE immunologist is the despair of the average medical reader, for he is constantly devising new terms to explain his discoveries and almost as rapidly discarding them as newer discoveries render the old terms untenable. There is also a further difficulty in the fact that a term devised by a foreign scientist has often to be incorporated into our vocabulary as it stands, because it is not readily translatable; as an example we may quote the terse but valuable term "subintrant," introduced by Besredka to describe his special method of preventing anaphylactic shock. To Besredka also, in conjunction with Steinhardt, we are indebted for the introduction of the term "anti-anaphylaxis," to describe the condition of insensibility to further injections of the anaphylactic antigen. We are doubtful if the term can really be regarded as a satisfactory one, and its wide use to cover a number of different immunological states has weakened its significance not a little. It would strengthen our claim to consistency if we confined this term to the actual state of being insensitive to the anaphylactic antigen, rather than enlarged it to cover the measures—often purely empirical—which the clinical pathologist devises to counteract anaphylactic symptoms in the patient. But the deed is done and the term anti-anaphylaxis now embraces in the minds of most physicians every aspect of desensitisation. In a valuable report[1] on this subject by MM. P. Widal, P. Abrami and P. Vallery-Radot, read before the French Congress of Medicine at Strasbourg in October, after defining anaphylaxis as colloidoclasia or "the rupture of the physical equilibrium of the colloids of the body," the authors proceed to lay down the various methods of desensitisation. As they correctly point out, a patient who has been deliberately sensitised with serum can be watched and protected from ill-effects after the second or anaphylactic injection, because the date of his first inoculation is, or should be, known. But in the case of patients who have become sensitised in some unknown way and at some remote time in their history, by absorption of protein through gastro-intestinal or respiratory mucous membrane, a different problem confronts the physician. He must first discover the protein which is at fault, and then resort to his armoury of protective measures, such as subintrant doses, or vaccination with homologous or heterogeneous proteins, administration of peptone, crystalloids—e.g., sodium chloride—or finally adrenalin. All these measures are fully discussed by the authors, and also by M. Pélin in a subsequent paper. They succeed in making anti-anaphylaxis a live issue whatever view may be taken of the term itself.

Our current number contains an original article by Prof. Storm van Leeuwen of Leiden, in which he records a series of cases of spasmodic bronchial asthma treated with tuberculin. Excluding army and from public bodies, and to-day the Ministry possesses accommodation in its neurological hospitals and wards for 167 officers and nurses and 3450 other ranks.

---

[1] Journal of the Royal Naval Medical Service, July and October, 1921.

[1] Presse Médicale, Oct. 1st, 1921, p. 781.

At the beginning much difficulty was experienced in securing the services of medical men specially qualified and experienced in modern methods of treatment of functional nervous diseases—for the war created a mass of neurasthenics quite out of proportion to the number of available experts in functional disorders; but by establishing a training school at Tooting for medical men interested in, and possessing some experience of, functional nervous diseases under the able direction of Dr. R. G. Rows, late c/o of the Military Hospital at Maghull, this difficulty was overcome. At Tooting some 68 men received systematic instruction in modern psycho-therapy. The neurological hospitals are now efficiently equipped and staffed; they possess ample garden space and in many cases farm lands, and there the treatment is directed, firstly, to curing the psycho-neuroses; and, secondly, by occupation selected after consultation between the medical officer, the chief training officer, and the patient himself, to preparing the latter for his return to outside conditions.

The usual occupations, each under expert instruction, include gardening, pig-keeping, poultry-farming, carpentering and cabinet-making, metal work, leather work, and boot-repairing. The proportion of patients usefully and happily employed for part of each day in the workshops and gardens of the neurological hospitals ranges from 30 to 40 per cent. to as much as 60 to 70 per cent. of the total number of patients. Accommodation is generally from 10 to 20 per cent. in excess of the number of beds occupied.

During the three months ended Sept. 30th, 1921, there were 399 discharged as recovered and 1003 discharged as relieved from Ministry neurological hospitals, giving a recovery and relieved rate calculated on the number admitted during the three months (2128) of 65·9 per cent.; or, calculated on the total number treated during the three months (5670), of 24·7 per cent. The out-patients treated at Ministry institutions during the same period gave a recovery and relieved rate of 63·8 per cent. calculated on the number admitted (3890); or, calculated on the total number of out-patients treated (11,576), of 21·5 per cent. The combined recovery and relieved rates for these three months were, therefore, 64·6 per cent. calculated on the admissions; or 22·5 per cent. calculated on the total numbers under treatment.

Borderline Cases.

The cases of officers and men suffering from psychoses attributable to, or aggravated by, war service and in whom the question of certification as insane arises, or may arise in the future, have always been regarded by the Minister with grave anxiety and concern. It has been, therefore, a cardinal principle to concentrate on these cases the medical resources of the Ministry in the hope of restoring health and averting certification, which latter is kept as a last resort. The Minister, as the law stands to-day, has, of course, no authority to treat officers or men properly certifiable as insane in any of his institutions, and the failure must be remembered of all attempts made to permit, with proper safeguards, the detention of mental cases likely to recover within a short time but requiring supervision, detention, and control. Clause 10 of the Miscellaneous Provisions Bill introduced last year by the Minister of Health was defeated.

For some time at the Maudsley Hospital and now at Ewell, in the case of other ranks, and also at Latchmere, in the case of officers, provision is made for the borderline class of case. These institutions are well equipped and staffed, and coupled with the neurological hospitals of the Ministry are ample for present needs. In addition to the in-patient accommodation referred to above, there are 56 neurological clinics, which, together with the out-patient departments of the neurological hospitals, afford treatment at the present time to 7664 out-patients.

Insane Ex-service Men.

Following conferences between the Statutory War Pensions Committee, the Asylum Authorities, the Board of Control, and the Ministry of Pensions, insane ex-service men whose mental disorder is accepted by the Ministry as due to, or aggravated by, war service are admitted to and treated in the ordinary mental institutions of the country—i.e., the county and borough asylums. No other course could have been followed and no other is even now advisable. The service patients, however, are placed on the legal footing of private patients at the cost of the Ministry of Pensions, and they are afforded certain other privileges (clothing of superior quality and 2*s.* 6*d.* a week for extra comforts). Further, by arrangement with the Board of Control the patients are visited by medical inspectors from the Ministry headquarters; and each man is interviewed and reported upon by these inspectors. In all other respects the service patients, other than ex-officers, are treated in exactly the same way as the ordinary inmates of these institutions. From the reports of the inspectors who have now interviewed over 5,438 patients in 120 asylums, the Minister is satisfied that the service patients are well cared for.

Numerous attempts have been made to discredit the conditions in the county and borough asylums, and by frequent reference to the "herding" of service patients with "pauper lunatics" to cast an unmerited stigma both on these excellent institutions and their inmates. It has even been stated that large numbers of men who are bereft of reason by their fighting service are "held in bondage" and their recovery prevented by being immured in asylums in which they should never have been placed. Such statements, whose only result can be to cause needless distress to the unfortunate relatives of service patients, are devoid of truth. The Minister's inspectors report that not one man has been interviewed who has been improperly certified as insane, and that the overwhelming majority is composed of cases of unfavourable character and prognosis, cases of original congenital defect, general paralysis, and dementia. Nevertheless, in a minority recovery, and in a larger number improvement permitting of discharge, is effected, averaging some 26·47 per cent. (recovered 17·41 per cent. plus relieved 9·04 per cent.). Prior to the war every million of male population between the ages of 20 and 44 years in England and Wales furnished 750 insane to institutions each year.

During the war, when so many millions of men were serving in the forces, there was a steady fall in admission to asylums, which immediately after the armistice began again to ascend, as shown by the following figures given by the Lunacy Commissioners:—

Admissions to Asylums in England and Wales.

Year.	Number.	Year.	Number.
1915	53,416	1919	41,727
1916	51,840	1920	42,428
1917	50,382	1921	44,004
1918	46,025		

Notwithstanding the obvious inference from these figures, and notwithstanding the opinions of medical superintendents of asylums, as, for example, that published by Dr. W. Robinson, of the West Riding Asylum,[1] showing that only 44 per cent. of the service patients in that asylum had served overseas in the firing line, and that "the service patients, as a class, would, as regards the majority, have been patients in mental hospitals sooner or later had there been no war," the Minister has extended the provisions of the Royal Warrants to practically every case of insanity arising during service or within a limited period after discharge, thus giving the ex-service man the benefit of any doubt that may exist.

The popular conception that all ex-service men in asylums are the victims of "shell-shock" is quite erroneous. This in no way, however, lessens the

---

[1] Service Patients in Mental Hospitals, by William Robinson, M.D., Senior A.M.O., West Riding Asylum, Wakefield. Journal of Mental Science, January, 1921.

In respect of life assurance, he said that the sums assured under new policies represented £85,000, with an annual premium of £2700, 84 policies having been negotiated in the period under review.

In respect of motor-car insurance he said :—

The placing of these risks has engaged the serious attention of the Agency in view of the fact that the premium rates were again advanced in April of this year. Not only have the rates in all the leading offices increased, but in the case of cars of small horse-power, minimum rates have been enforced. For example, a car of 12 h.p. originally costing £400, which by use and age has decreased in value to £250, is assessed in premium at the same rate as a new car of similar horse-power and a value of £400. The Agency realising that such a decision would cause dissatisfaction to many of the insured persons on renewal, took the matter up with the principal company accepting these risks. The explanation given was that for some years offices accepting motor-car risks had steadily lost money, culminating in somewhat serious losses in 1920. An unduly large percentage of the claims arising under motor-car policies were found to be among the smaller horse-power cars, and it was for this reason the minimum rate was introduced. The Agency has received many complaints as to the method of assessment, but in most cases has been able to retain the insured and secure a renewal.

There was reported also by the Chairman a steady increase under the headings of the fire, household, and accident insurances, the advice of the Agency being regularly sought in the choice of suitable contracts. For household purposes the Agency is recommending, said the report, the taking of full comprehensive policies, while by arrangements with Lloyds, medical men can secure through the Agency policies against a form of larceny to which they are special victims—namely, robberies from surgeries and waiting-rooms.

The Chairman commented on the fact that although progress had been so marked only a small number of medical men had as yet taken advantage of the facilities offered, considering the number of practitioners on the Register, and considering also that through the courtesy of the British Medical Association the Agency enjoys the privilege of distributing inquiry cards with all the applications for subscriptions to the Association. In this connexion Dr. Haslip acknowledged the particular indebtedness of the Agency to the medical secretary of the Association for his interest and for his action in appealing to the officers of the organisation of the Association to make the work of the Agency more widely known.

Finally, Dr. Haslip recommended that the Committee should make further grants to medical charities, for which purpose a sum of £1055 was available, being the whole of the surplus in hand.

Grants to Medical Charities.

The report of the Chairman having been received and approved, the following grants to medical charities were approved: Royal Medical Benevolent Fund, £315; Royal Medical Benevolent Fund Guild, £315; Epsom College Benevolent Fund, £315; Royal Medical Benevolent Fund Society of Ireland, £25; Birmingham Medical Benevolent Society, £25; Lincolnshire Medical Benevolent Society, £25. As a result of this distribution the total sums now voted by the Agency to medical charities reaches £8400, while the amount distributed in the past year is exactly £2000.

The Committee of Management.

Having regard to the growth of the work of the Agency and the amount of money which is and will be available for distribution, Sir Dawson Williams raised the question of increasing the number of those serving on the Committee. It was resolved that a suitable list of names from among those already insured through the medium of the Agency should be prepared in order that a certain number of representative practitioners may be invited to join the Committee.

Food Poisoning at Clitheroe.—A compendious report on the recent outbreak of ptomaine poisoning at Clitheroe has been presented to the Borough Health Committee by Dr. W. E. Barker, medical officer of health, who concludes that "a crude working knowledge of the rudiments of bacteriology would appear to be a necessary equipment in the public catering profession."

STUDIES IN MILK.

By R. Stenhouse Williams, B.Sc., M.B., C.M. Edin., D.P.H. Camb.,

RESEARCH BACTERIOLOGIST IN DAIRYING TO THE MINISTRY OF AGRICULTURE AND FISHERIES.

In a recent leading article[1] dealing with a Clean Milk-supply mention was made of the important work now being carried out at the National Institute for Research in Dairying. This Institute was founded in 1913 at University College, Reading, in order to help to improve the milk-supply of the country, in the belief that help coming from within the milk industry itself was likely to prove the surest way of promoting progress.

Losses Found in the Milk Industry.

Work upon this subject began in 1916, as the result of an inquiry[2] concerning the losses and causes of loss which were being incurred by the milk industry. Table I. shows the losses which were found to be incurred in the two districts from which statistics were obtained. In district 2 it was only possible to estimate the losses from souring, but there is no reason to suppose that the other sources of loss differed materially from those found in district 1.

Table I.—*District 1.*

—	Gallons of milk annually.	Value at 1*s.* a gallon.
Total supply	90,000,000	£4,500,000
Losses—		
(1) 1 % sour	900,000	45,000
(2) 3 pints per churn lost by splashing	1,965,441	98,272
(3) 10 % pasteurised at ½*d.* a gallon	8,713,455	18,153
(4) Irregularity of supply and demand necessitating purchase of accommodation milk and sale of surplus at a loss, 1*d.* a gall.	—	375,000
Total losses		£536,425

These losses represent a sum of about one-ninth of the monetary value of this supply.

District 2.

Total supply	75,000,000	£3,750,000
Losses— 1–2 % sour (at 1 %)	750,000	37,500

These losses were estimated at a time when the price of milk was much lower than it is now and the figures would need to be revised for money values at the present time. This inquiry led on to the taking of steps at the Institute to prevent the loss by souring and consequently a great deal of the need for pasteurisation.

Comparative Studies of Clean and Average Commercial Milk.

It may be said by way of preface that at the time these losses were discovered the country was at war, the Institute possessed neither cows nor dairy of its own, and the staff was very limited in number. It was not possible, therefore, to study the subject from all sides at once, and a beginning was made by the study of the cleanest commercial milk which could be found, in comparison with an average milk which was certainly no worse than much of that on the market. It was hoped that in this way knowledge might be gained of the relative states of average commercial milk and of the cleanest commercial milk that was known. In carrying out the work it was necessary to consider, not only the bacteriological content of the two types of milk, but also the periods of time during which each type remained sweet, for it is by the duration of sweetness peutic agencies, the use of which should be regarded as permissible only to doctors of medicine. The substance of the report is as follows.

Public demonstrations of such a nature by non-medical men are always promoted from a financial standpoint, and constitute a nuisance. Permission to hold such demonstrations should not be granted, as they tend to upset the nervous systems of many spectators, and may cause severe harm, especially through the agency of the mediums who volunteer to help the demonstrator. If a lay person is licensed to give public demonstrations of telepathy and occult phenomena, there is always the danger that mercenary considerations may overcome his discretion; and criminal influence is not always beyond question. Occult phenomena have commanded widespread interest since, and perhaps on account of, the war. To be successful experiments always require increased susceptibility and suggestibility of the medium; they tend to cause nervous conditions in many persons, whereas it should be the object of public health officials to restore the nervous equilibrium of the population. Public feeling should therefore be roused against the exploitation of manifestations of nervous conditions not yet scientifically explained and detrimental alike to the individual and the community. This report, together with an order to stop all such exhibitions, has been circulated among municipal officials throughout the country. The actual bad effect upon persons predisposed to nervous instability has been observed in several instances brought to public notice in a couple of forensic cases during the last few weeks. Either crimes were attempted by means of hypnotic influence, or permanent ill-health was caused; in one instance the hypnotist was unable to rouse his medium from the trance, and the victim had to be taken to hospital.

Dec. 14th.

CANADA.

(FROM OUR OWN CORRESPONDENT.)

Public Health in Toronto.

Dr. Hastings, M.O.H., Toronto, recently announced the city's death-rate to be the lowest for some time, the rate for the last ten months being 11·3. Cancer and heart disease account for the largest number of deaths. The infantile mortality rate continues to be the lowest yet recorded. The principal cause of deaths was premature birth, a cause which will be reduced only by increasingly intelligent care of the mother during pregnancy. An alarming increase in the number of cases of diphtheria is shown in the November report of the Provincial Board of Health. There are 940 cases of this disease throughout the province, as compared with 55 cases for November last year; while the death-rate is 82, as compared with 43 in the corresponding period in 1920. The disease is not so prevalent in Toronto as in outside centres. It is said to commence in a mild form in those it attacks and later to increase in virulency. The Board of Control of the city of Toronto recently voted an additional $7500 to enable the Department of Health to continue its work in social welfare until the end of the year.

University News.

The popularity of the graduate courses held by the Faculty of Medicine of the University of Toronto last December and May has led to arrangements being made to hold similar courses this month. Provision has been made for a course in surgery, one in medicine, and one in gynæcology and obstetrics, to be run concurrently from Dec. 19th to 24th. Under this arrangement it will be possible for a candidate to avail himself of more than one course. The courses will be limited to a registration of 60. It is considered that a week's concentrated work in a large hospital will produce better results than it is possible to obtain in the extension lectures which are now being given throughout the province by the Faculty of Medicine.

Prof. William Bateson, F.R.S., Director of the John Innes Horticultural Society, Merton Park, Surrey, England, will give five lectures on Genetics and Heredity in the medical building of the University of Toronto in the early part of January, 1922. The University of Toronto Memorial Loan Fund applications for funds to enable returned soldier students to continue their courses may total 189, as announced recently by the Alumni Scholarship Board. Already 122 applications have been recommended. The Faculty of Medicine is applying for 55 loans for a total of $10,535.

Results are now coming from the generous gifts made to the University for the furtherance of the study of medicine by Sir John Eaton and the Rockefeller Foundation. Sir John and Lady Eaton have donated $500,000 to the University to be paid in 20 annual instalments. The gift from the Rockefeller Foundation is a million dollars.

The Medical College of the Western University, London, Ont., was formally opened recently by Dr. Grant, Minister of Education for the Province of Ontario. The building was erected and equipped at a cost of over half a million dollars.

Beri-Beri in Labrador.

Dr. Wilfred T. Grenfell, Labrador, Canada, at a recent address before the Empire Club, Toronto, Canada, spoke of the campaign against beri-beri, a form of sleeping sickness prevalent in the isolated districts of Labrador, where the food consumed is chiefly fish diet. Dr. Grenfell is at present in Canada conducting a campaign to raise funds for the hospitals, schools, and orphanages he has established on the Labrador coast.

Prescriptions for Liquor.

Chief Inspector J. N. McLean stated recently that only 10 per cent. of the physicians practising in Manitoba issue their limit of 100 prescriptions for liquor each month. If all the doctors prescribed their allotment, 68,300 orders for liquor would have been filled by drug stores, whereas about 14,000 prescriptions are actually issued.

ROYAL MEDICAL BENEVOLENT FUND.

AT a meeting of the Committee held on Dec. 13th 28 cases were considered, and £378 10*s.* voted to 25 of the applicants. The following is a summary of some of the cases relieved:—

Widow, aged 63, of L.R.C.P. & S., who practised at Credbury Mortimer, London, was latterly a surgeon on a Union Castle boat and died this year. Applicant is left quite unprovided for, suffers badly from rheumatic gout, and is unable to earn her own living. She receives £5 interest from War Loan and has sold various articles to pay her way. From Dec. 31st, 1921, the steamship company have granted her £50 for two years. At present her rent is 30*s.* per week for two rooms. Voted £10 in two instalments.

M.R.C.S. Eng., aged 59, who practised at Penarth up to 1892. Through paralysis had to give up practice. He now has to pay £2 2*s.* per week for attendance, board, and lodging, and his only income is an annuity of £72 3*s.* per annum and £35 from friends. A son, who used to help, died in 1918, and a brother, who formerly allowed a small sum, is unable to continue help. Voted £26 in 12 instalments.

Daughter, aged 78, of M.R.C.S. who practised at Southsea and died in 1884. Applicant's income is derived from investments amounting to £30 and £50 from nieces and a nephew. Her sister who died recently was in receipt of an annuity from the Fund. Applicant's rent is £41 per annum. Voted £18 in 12 instalments.

Widow, aged 57, of M.B. Aberd. who practised at Regent's Park and died in 1910. Owing to ill-health applicant is unable to earn her own living and at present she is only in receipt of 30*s.* per week from a daughter. Voted £5.

M.B. Edin., aged 56, who practised at Milnathort. Owing to deafness he had to give up his practice and recently has been working as a gardener, but has found the work too heavy. He is now dependent on an unmarried sister whose means are insufficient for two people. Voted £26 in 12 instalments.

Subscriptions may be sent to the hon. treasurer, Sir Charters J. Symonds, at 11, Chandos-street, Cavendish-square, London, W. 1.

INFLUENZA EPIDEMIC IN ROSSENDALE.—Owing to the prevalence of influenza in the Rossendale Valley the schools in Rawtenstall have been closed. Other parts of the district are also affected.

12 hours, with an average of not more than nine hours, at a time when any serious proliferation of organisms in clean milk does not take place. The cows were out to grass, and cleaner than in the winter-time, and the cowshed was empty except when the cows were being milked. The conditions appeared to be favourable to a cleaner milk production, yet as a fact it was dirtier. The utensils, however, were washed with only moderate care and were not steamed. It appeared probable that, in the warm weather and in their moist condition, they were a serious source of contamination to the milk. Confirmation of this probability was obtained by Cumming and Mattick,[6] who demonstrated the condition in which milk-churns are being returned to the farmer.

TABLE IV.—*Classification of 500 Churns by Inspection. Oct. 9th–Nov. 20th, 1919.*

Clean and sweet.		Milk absent. Evil smell.		Churn not washed. Milk present.	Churn badly washed.
Dry.	Wet.	Dry.	Wet.		
81	110	5	118	81	75
16 %	28 %	1 %	24 %	16 %	15 %

Table IV. gives a summary of the results which they obtained, and the results of the bacteriological examinations of these churns further confirmed the observations they had made since they demonstrated that very few, even of those churns which were clean and sweet and dry, had been efficiently washed and steamed before they were returned to the farmer. This is well brought out in Table V. and is an illustration of the need, not only for greater knowledge of the method necessary to attain the object desired, but also for more coöperation within the industry. If the interests of the producer, the wholesaler, and the retailer were identical, such churns would not be returned to the farmer; since in the first place it is very difficult to wash and steam a churn properly when it has travelled, perhaps for 24 hours, before the washing takes place; and in the second place, there are many dairy-farms in the country on which the water-supplies are inadequate for this work.

TABLE V.—*Bacteriological Examination. Oct. 9th–Nov. 20th, 1919.*

Condition of churn.	Counts.	Acid and gas in litmus-lactose-peptone water.
Unwashed (whole milk present)	∞ in 1/100,000	+1/100,000
	4,000,000	+1/100,000
Badly washed (milky water present)	∞ in 1/10,000	+1/10,000
	18,400,000	+1/1000
Apparently clean but wet	5,300,000	+1/1000
	4,100,000	+1/100
	780,000	+1/10,000
	610,000	+1 c.cm.
Apparently clean and dry	6,200,000	+1/1000
	1,720,000	+1/10,000
	1,600,000	+1/100
	800,000	+1 c.cm.
	400,000	+1/1000
	35,000	+1/10
	15,400	+1 c.cm.
	6,500	—
	5,000	+1/10
	3,000	—
	2,100	—
	2,000	—
	170	—

Throughout this work it became clear that the proper methods of efficient washing and sterilisation were not understood within the milk industry, and the need for further knowledge on these subjects was more obvious still when visits were paid to milk depôts of various kinds, nearly all of which possessed steam but made use of it in an ineffective manner. Investigations were, therefore, carried out in order to establish the minimum times that are required for the sterilisation of milking utensils, especially milk-churns, for commercial purposes. That work has now been one by Hoy[7] and Mattick[8] and the times and conditions necessary for efficient sterilisation, either by current steam or by steam under pressure, have been established.

Conclusions.

Such is some of the work carried out at the Institute during the past five years which has established certain important facts. First, that the best produced commercial milk can maintain a bacteriological standard of less than 10,000 colonies per 1 c.cm. for at least 24 hours after milking, even under the conditions of cooling and transit which exist in this country at the present time. Second, that such milk maintains its sweetness at room temperatures for a period of time which averaged 6·2 days in the winter months and 3·3 in the summer months. Third, that milk of a very high degree of cleanliness can be obtained in an average cowshed if the right worker be employed and be given light, water, steam, and a covered milking bucket. Fourth, that much of the contamination of milk is due to utensils. Fifth, the conditions necessary for the efficient sterilisation of dairy utensils, whether by current steam or by steam under pressure, have been established.

These and similar investigations have been of use to the producers of Grade A (Cert.) and Grade A Milk in their work. They have promoted coöperation within the milk industry and have improved the methods of education in our dairy schools.

MENTAL DISEASE IN EX-SERVICE MEN:

WORK OF THE MINISTRY OF PENSIONS.

THE care of soldiers and sailors who took part in the war and whose minds became affected during their service has been one of the most anxious tasks committed to the Ministry of Pensions, and one that has brought it into a cross-fire of criticism from many directions. We summarised recently (THE LANCET, Dec. 10th, p. 1232) some of the searching questions asked in the House of Commons upon the subject, briefly commenting upon the official answers and what lay behind them, and we are now in a position to state with official authority the provision for these unfortunate cases as it exists at the present moment. Separate provision is made for (*a*) cases of neurasthenia; (*b*) cases of severe neurasthenia, the so-called "borderline" cases; and (*c*) the certified insane.

Cases of Neurasthenia.

In the early days of the Ministry of Pensions, before the re-organisation of the medical services, the victims of war neuroses, so-called shell-shock and kindred ailments, were treated either in the special neurological hospitals of the army and navy or in hospitals managed by Local War Pensions Committees and Joint Disablement Committees acting as agents of the Pensions Minister. A small number of "Homes of Recovery" directly controlled by the Ministry also accommodated a certain number of pensioners suffering from neurasthenia. With the creation of the regional organisation of the Ministry, however, special neurological hospitals and wards of hospitals were established in each region. Hospital after hospital was taken over from the officer of the district. The nurses, too, undertake the whole of the health work in the area allotted to them, including the following up of ailing children. In this they are assisted to a limited extent by the Society for the Prevention of Cruelty to Children and the local committees dealing with infant welfare work. Minor ailments are treated at the school treatment centres, but diseases not coming under this heading are attended to by the school nurse at the instance of the general practitioner in charge of the case. There is one experimental nursery school in the county. A thorough investigation into the school furniture in *use in schools has been held, but unfortunately few* recommendations for its improvement were suggested. Dr. Greenwood believes that even if a fresh start could be made any scheme adopted would still remain imperfect, and to some extent experimental. Analysing the seating accommodation for 24,311 children, he reports that 7000 had seats without backs, and 2000 had chairs and tables. He is not quite satisfied that tables and chairs are the right thing for children, and, as a matter of fact, experience has shown that, wherever tables have been introduced, except for infants, they have been replaced later by more specialised furniture. The modern tendency to revert to tables and chairs for older children is a temporary phase, and sooner or later the desk will reassert its superiority.

Dr. Greenwood admits the great importance of good lighting, but records that his personal view is that bad lighting has not yet produced a case of eye disease. This may be so, but the fixation of the eye required in bad light is an urgent cause of eye-strain. In an eye predisposed to myopia this strain certainly aggravates the diseased condition. Eight per cent. of the school population in Kent suffer from defective vision, and 2 per cent. from squint.

An analysis of the ages of children suffering from diagnosed or suspected tuberculosis showed that, excluding disease of the glands, there was no difference in the numbers at the ages of 8 and 14 respectively.

SWINDON.

Out of 2632 children examined, 213 were found to have defective vision, 279 enlarged tonsils, 61 of these requiring active treatment. Only one case of rickets occurred, and there was no definite pulmonary tuberculosis. Dental examination of 2120 children revealed 17·3 per cent. with carious teeth; 1000 of these children received treatment under the local authority's scheme. Dr. Dunstan Brewer, successor to Dr. W. F. J. Whitley, reports that for years past Swindon has remained comparatively free from acute poliomyelitis, but that, on the other hand, rheumatism is a common disease, and cardiac cripples are numerous. Four cases of organic heart disease were discovered at medical inspections. Dr. Brewer looks upon diphtheria as "the great killing disease among children of school age," and is of the opinion that the school teacher is much more likely to be the carrier than are the children; he suggests that when throats are being swabbed the teacher should *not be forgotten*. Commenting on voluntary help, it is stated that the need has been lessened considerably, and that voluntary workers, forming children's care committees and so forth, were now less essential to success than when school inspection was first inaugurated.

The coöperation between the school medical service and local infant welfare work is so close that it is hoped shortly to have a continuous health record of each child between birth and the age of 16.

DONATIONS AND BEQUESTS.—The Manchester Royal Infirmary has received £1000 from the late Mr. Marcus Morreau for the endowment of a bed, a bequest of £100 from the late Mr. Joseph Milnthorpe, and £250 from the late Mr. Joseph Stanier. Donations from Salford and Glossop and from employees of various firms reached £315, while the Manchester Ship Canal Company have increased their annual subscription from £25 to £100. The subscriptions and donations to the Manchester Children's Hospital during the past month reached £816, including £500 from Messrs. Peel and Co., Ltd.

ORGANISATION OF MEDICAL EDUCATION: OPHTHALMIA NEONATORUM.

To the Editor of THE LANCET.

SIR,—Mr. J. Herbert Parsons, in your columns last week, drew attention to the inefficiency of the present curriculum in teaching the medical student how to cope with ophthalmic conditions, more particularly ophthalmia neonatorum. The Metropolitan Asylums Board have established a special hospital for this disease—namely, St. Margaret's, Leighton-road, Kentish Town. Last year rather less than one-third of the cases which occurred in the London area were received at this institution. A large percentage were blind on admission from corneal ulceration owing to inefficient or want of early treatment. Indeed, the average day on which they were admitted to the hospital was the ninth. One can only put this down to ignorance on the part of the midwife or doctor attending the cases, as if they had been educated in the natural history of the disease during their curriculum *this would not have occurred. In 1020 the Ophthal-*mological Society of the United Kingdom passed the following resolution:—

> "In passing a vote of thanks to the Metropolitan Asylums Board for permission to visit St. Margaret's Hospital, this meeting of the Ophthalmological Society wishes to urge on the Board, now that so large a number of cases of ophthalmia neonatorum are congregated together in one institution, that facilities should be afforded at their hospital for the teaching of medical students, midwives, and district nurses the natural history and treatment of the disease."

As the result of this the Metropolitan Asylums Board gave permission for St. Margaret's Hospital to be used for the purpose of teaching, and all the examining bodies were informed both of the resolution and the permission given by the M.A.B., but so far no advantage has been taken of the facilities so offered.

I am, Sir, yours faithfully,

Harley-street, W., Dec. 26th, 1921. M. S. MAYOU.

INTERPOSITION OPERATION FOR VAGINAL PROLAPSE.

To the Editor of THE LANCET.

SIR,—Last year you published[1] a lecture I had delivered at the Royal Society of Medicine on the surgical treatment of prolapse of the uterus and vagina. In this lecture I made the following statement in regard to the interposition operation:—

> "Schauta, to whom the introduction of this operation is attributed, lost five cases in 89 operations, and in 13 cases there were recurrences. Fothergill, commenting on these figures, justly remarks that 'no results could be much worse than these.' Bissell has reported an almost incredible mortality of 75 per cent., while Vineberg[2] states that 'I abandoned it (interposition operation) myself on account of the extensive suppuration usually accompanying it.'"

I explained in another part of the lecture how sepsis can be entirely prevented. When I was in America this year I met Dr. Bissell, with whom I discussed the matter. He then told me he had not made any such statement as that attributed to him; for, like myself, he had never had a death following the interposition operation. This information was so contrary to what I had quoted in my lecture that I asked him to make some inquiry into the matter. I have just received from him a letter enclosing one from Dr. Vineberg, which explains how the mistake has arisen. I shall be very glad, therefore, if you will publish these letters, which I enclose, as I greatly sympathy with which each service patient is regarded, or diminishes the Minister's anxiety that the patient should receive the utmost care and most skilful treatment. The proposal that special asylums should be created solely for ex-service men has been much discussed. The general public, unversed in such matters, unaware that the first necessity for proper treatment is proper classification and segregation according to behaviour, conduct, and medical category, and that, therefore, treatment can only be properly carried out in institutions of sufficient size to permit separate wards according to classification, naturally fails to appreciate the necessity for institutions of considerable size and accommodation. Of this necessity, however, medical men are well aware. It would, therefore, be necessary, if popular demands are to be met, to create some 12 or more institutions for service patients placed at convenient centres.

---

[1] THE LANCET, 1920, i., 993.

[2] Vineberg, H. N., Amer. Journ. Obstet. and Gynecol., 1919, lxxix., 677.

Bearing in mind the indisputable fact that the service patients do not differ in medical category and conduct from the ordinary patients of asylums, and that as regards the great majority the prognosis is no more favourable than in their unfortunate fellow patients, the accommodation provided should be as complete in every detail as that provided for civil patients. The county and borough asylums with their separate wards varying in number from 8 to 20 on the male side; special electrical and X ray plants; isolation rooms and safety appliances; separate exercise courts according to class of case; laundry and workshops; garden and farm lands and buildings would all be required for a class of patient whose numbers should now be at their maximum and will necessarily steadily decline to zero in, say, 30 to 40 years' time. No one even superficially acquainted with the subject would propose temporary accommodation of the camp or hutted type as suitable for such cases. What, however, has been seriously proposed is the setting apart of selected county and borough asylums for service patients only. This proposal is not without its merits, but has the great disadvantage that it would necessarily, in a large proportion, probably the majority, of the patients, remove the patient so far from his relatives and friends that he and they would be deprived of one of their greatest solaces, the frequent and periodic visitation and intercourse.

Intermediate between these two proposals the setting apart of special blocks of existing asylums for service patients who no longer require strict supervision and who may enjoy and benefit by a greater degree of freedom, a more domestic type of surroundings and occupational treatment, and even vocational training, in fact a half-way house between the asylum and ordinary civil life, though remaining within the general asylum administration, has been under consideration for some time following the recommendations of the Departmental Committee of Enquiry into the Ministry of Pensions administration.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Anti-Tuberculosis Work in Austria.

IN order to inform medical practitioners of the available means of combating tuberculosis, the Board of Health has issued a small booklet containing all data concerning welfare institutes, hospitals, and sanatoriums devoted to the treatment of this disease. Three distinct groups of institutions exist for this purpose in Austria. First, there are the 43 so-called welfare centres, situated in the densely populated districts of Vienna and the larger provincial towns, and under the control of fully competent lung specialists, aided by two or more fully trained nurses. Their object is the dissemination of information to patients concerning hygienic modes of living, prevention of infection, assistance in procuring hospital beds n cases of necessity, and control of the convalescents heir homes. In numerous centres regular tuberculin es are given to chronic cases not requiring hospital treatment. The second group consists of the 27 sanatoriums for internal or for surgical tuberculosis, situated in mountainous or hilly country districts esteemed for their equable climate. Altogether they contain a little over 3400 beds, with about 960 beds for children. Quite 50 per cent. of these institutions are owned by the State or the provinces, and are thus open to the poorer classes; the remainder are private, and conducted for profit. The majority are possessed of modern apparatus and appliances for physio- and mechano-therapy, including X ray and quartz-light plant; some of them are situated high up in the Alps, where the therapeutic effect of sunlight is utilised. The third group comprises about 5700 beds in hospitals, for both internal and surgical tuberculosis, for patients of both sexes and of all ages. In Vienna alone 3400 beds are available for this purpose; about 25 per cent. of all these beds can be used for children. The remainder of the beds are divided up between the hospitals in the country districts and provincial towns. Vienna contains about 30 per cent. of the entire population of the republic, but has 60 per cent. of the tuberculosis beds. In the whole country there are 89 public hospitals, with a capacity of 26,776 beds, and 124 private hospitals with 5706 beds, or a total of 32,482 beds, of which figure 18 per cent. are devoted to patients suffering from tuberculosis. This figure—18 per cent.—represents a not quite sufficient proportion of space allotted to tuberculosis.

Prohibition of Yellow Phosphorus.

The Austrian Republic has accepted the Convention of Berne, which prohibits the use of ordinary yellow phosphorus for the purpose of making matches. It is interesting to realise that it took 15 years for the provisions of this convention to be put into force in this country; only by means of the Peace Treaty was it possible to compel interested parties to accept this absolutely necessary public health measure. Only a few of the great factories have hitherto been wise enough to study the social welfare of their employees; now and then the students in the Vienna clinics have had the opportunity of observing a case or two of phosphorus-necrosis, but some 25 years ago the disease was so frequent here that Prof. Albert wrote a monograph on it, and showed cases to his students at every class. Strong feeling also exists here against the proposed prohibition of the use of lead in factories for paints and dyes; and with regard to the disinfection of raw wool imported into Austria the manufacturers of the country are again not quite as advanced as is desirable in matters of modern prophylactic medicine.

Dangerous Dental Fillings.

The attention of the medical profession, and especially of dental surgeons, has been called to the existence of dangerous compositions, widely advertised as a substitute for gold, for filling teeth and bridge and crown work. These alloys, consisting of copper and zinc, are similar in their constitution to tombac, but also contain lead, some even as much as 0·5 per cent. These metals are not as resistant to the action of alkaline or acid liquids as are the copper-gold alloys; they are therefore subject to constant dissolution under the influence of saliva in the mouth. Small quantities of lead are thus being constantly thrown into the system. Toxic conditions may result, and have been observed. The alloys have been widely used owing to the great difference in their prices when compared with those of copper-gold alloys.

Spectacular Hypnosis.

For some time past public demonstrations of "telepathy" and hypnosis have aroused much comment both in the lay press and in medical circles. Certain disagreeable consequences having followed in some cases, the Board of Health has thought it necessary to interfere, and has issued a report to the Ministry of Health with the request to instruct magistrates and other authorities who license public meetings that hypnosis and suggestion are to be considered as thera-

HARRY LITTLEWOOD, C.M.G., F.R.C.S. ENG.,

LATE PROFESSOR OF SURGERY IN THE UNIVERSITY OF LEEDS; LATE LT.-COL., R.A.M.C.

It is with great regret that we record the death in his sixty-first year of Colonel Littlewood, which took place suddenly at Erpingham Lodge, Aylsham, Norfolk. At the age of about 53, Mr. Littlewood found the demands of an extensive consulting surgical practice too much for his strength, and he decided to retire and to settle in his native county of Norfolk, where he had purchased a small estate and where it was hoped that, fond of country life as he was, he would have many years to enjoy his well-earned retirement. This was about 16 months before the outbreak of hostilities and the war saw him back at once at the scene of his former labours, for he had in 1908 accepted a commission as Lieut.-Col. in the R.A.M.C.(T.) on the staff of the Second Northern General Hospital. Acting first as officer-in-charge of the surgical section, and very soon as Administrator in succession to Colonel Dobson, whose serious but happily temporary illness laid him aside for some time, he stuck to his work till, after the peace, the hospital was transferred to the Ministry of Pensions. Then for the second time he left Leeds, having during the strenuous years of the war shown marked powers of organisation, the keystone to a life of great usefulness.

Trained as a student at University College, London, where he was awarded the Atkinson-Morley scholarship in Surgery, he took the Fellowship of the Royal College of Surgeons of England, and was elected resident surgical officer to the General Infirmary at Leeds in 1886. From the beginning of his career in Leeds it was clear that he was destined to make his mark. He at once became popular with the staff, with his resident colleagues, and with the students, to the instruction of whom he devoted much time. Many improvements in dressings and in surgical technique owe their introduction to the Infirmary to his initiative, and the position of resident surgical officer was never more worthily filled than during his tenure of office. Shortly after he left the Infirmary and started as a consultant in surgical work he was elected assistant surgeon to the Infirmary. This was in the year 1890; after six years on the assistant staff he was promoted to the full staff and had charge of beds for 17 years. Though he had not felt able to complete the term of 20 years, which in Leeds is the limit imposed upon the members of the full staff, he was, on the recommendation of the Board, elected a consulting surgeon by the managers of the Infirmary. He received the honorary degree of M.Sc. in the new University of Leeds, and later was appointed Professor of Surgery.

One who knew him well, was one of his resident colleagues, and was closely associated with him throughout the whole of his life in Leeds, writes as follows: "As a teacher Littlewood was eminently successful; his knowledge was extensive and sound, his mind was clear and logical, his sympathies were wide and sincere. It was no wonder that he was popular with the students and that they trusted and respected him. He brought to bear upon his surgical work those gifts of skill, patience, judgment, and humanity which are all essential for true greatness in surgery. I would venture to say that his chief characteristics as a surgeon were indomitable perseverance, reasonable optimism, and imaginative faculties regulated and restrained by wise caution. Trusted by those who called him in consultation, he soon developed a large consulting practice, and he maintained and increased the reputation for surgery which has been enjoyed by Leeds for so many years. As a man he was absolutely straight, loyal to those with whom or under whom he worked, as well as courteous and fair to those who worked under him. His death leaves a blank in the minds of a large circle of friends both in the profession and among the members of the general public. He served the Infirmary and the University with single-minded honesty of effort and placed both institutions under a deep debt of gratitude."

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surgn. Lieut. H. F. Stephen to be Surgn. Lieut.-Comdr.

The following appointments have been notified:—Surgn. Comdrs.: F. C. B. Gittings to *Repulse*; H. P. Jones to *Victory*, addl., for R.N. Barracks, Portsmouth; A. H. H. Vizard to *Dryad* (Navigation School); S. Roach to *President*, addl., for R.N. College and Hosp. School, Greenwich; R. S. Osborne to *Orion*; P. H. M. Star to *President*, addl., for R.N. Recruiting H.Q.; N. H. Harris to *Crescent*, for Rosyth Dockyard; L. M. Morris to Woolwich (*temp.*); W. E. Gribbell to *Vivid*, for Devonport Dockyard; W. H. Hastings to *Inconstant*; W. H. Pope to *President*, addl., for recruiting duties, Southampton; R. J. Mackeown to *Vernon*; and D. H. C. Given to *Victory*, for R.N. Barracks, Portsmouth, on technical staff of Commander-in-Chief, as Naval Health Officer.

ROYAL ARMY MEDICAL CORPS.

J. O Cuthbertson, late Capt., R.A.M.C., T.F., to be Temp. Capt.

Maj. R. J. Cahill relinquishes the actg. rank of Lt.-Col.

Capt. C. H. Stringer relinquishes the temp. rank of Maj.

Temp. Capts. relinquishing their commns. and retaining the rank of Capt.: H. P. Hodge and H. J. Brink.

TERRITORIAL ARMY.

Capt. P. B. Spurgin to be Maj.

Maj. F. G. Hobson to be Lt., and relinquishes the rank of Maj.

Capt. R. L. Williams, from 5th Bn., Welch R., to be Capt.

Capt. W. A. Robertson, from T.A. Res., to be Capt.

Lt. A. S. L. Malcolm to be Capt.

Lt. J. Bowen-Jones (late R.A.M.C.) to be Lt.

Capt. M. T. G. Clegg resigns his commn. and retains the rank of Capt.

The undermentioned officers, having attained the age limit, are retired and retain their rank except where otherwise stated: *Lt.-Cols. C. A. Goullet, J. W. Nicholson, and* D. Smart (granted the rank of Col.), with permission to wear the prescribed uniforms. Majs. J. Cameron, V. Graham, D. A. Hughes, J. P. Brown, S. F. Barber, H. Stallard, and R. P. Ryan. Majs. (Bt. Lt.-Col.) H. W. Laing and P. B. Spurgin (retain the rank of Maj.). Capts. (Bt. Maj.) A. A. Jubb and A. Ricketts (granted the rank of Maj.). Capts. T. N. Thomas, J. R. Garrood, F. F. C. Jagger, R. L. Wood, H. W. Godfrey, T. R. W. Atkins, G. Higginson, and *J. A. Parsons.*

Capt. J. M. Kirkness relinquishes his commn. and retains his rank.

Supernumerary for Service with O.T.C.—Capt. A. E. Webb-Johnson, from Genl. List, R.A.M.C., T.A., to be Maj. for service with the Med. Unit of the Lond. Univ. Cont., Sen. Div., O.T.C.

ROYAL AIR FORCE.

The undermentioned Flight-Lieuts. are granted permanent commns.: W. F. Wilson, P. A. Hall, H. B. Troup, E. G. O'Gorman, and T. J. X. Canton.

INDIA AND THE INDIAN MEDICAL SERVICE.

Maj. S. S. Broome, professor of surgery, and Maj. J. J. Harper Nelson, professor of materia medica, have each been granted eight months' combined leave. Dr. H. Roberts has been appointed temporarily as Civil Surgeon, Khasi and Jhantia Hills, vice Maj. L. B. Scott, granted leave. Lieut.-Col. H. M. Mackenzie, of the Medical College, Lahore, has been granted one year's leave, and Lieut.-Col. F. A. F. Barnado, of the Medical College, Calcutta, four months' leave. Maj. E. C. Hodgson *officiates as Assistant Director-*General, I.M.S., at Simla.

ROYAL INSTITUTE OF PUBLIC HEALTH.—The *annual Congress will be held at Plymouth from May 31st to* June 5th. Lord Fortescue will preside and the Congress will be conducted in four sections:—Sect. I., State Medicine and Municipal Hygiene. President: Dr. D. Llewelyn-Williams. Sect. II., Naval, Military, and Air. President: Surgeon Rear-Admiral Sir Daniel McNabb. Sect. III., Bacteriology and Biochemistry. President: Prof. J. Martin Beattie. Sect. IV., Women and Public Health. President: Lady Astor. The Harben lectures will be delivered during the meeting by Dr. T. Madsen, Director of the State Serum Institute, Copenhagen. Further information may be obtained from the offices of the Institute, 37, Russell-square, London, W.C. 1.

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

BLACKBURN.

Dr. W. Allen Daley submits an interesting report, and mentions as the outstanding features of the year: (1) the lowest general death-rate (12·7) ever recorded in the town; (2) the lowest death-rate from tuberculosis (0·79); (3) extension of maternity and child welfare work; (4) inauguration of work with the object of educating the public on health matters; (5) progress, howbeit slow, with the erection of municipal houses. The Registrar-General's estimate of the population for 1920 is 131,012, but Dr. Daley, from various sources of information, thinks this figure too low, and adopts an estimate of 140,000. The provisional census returns apparently justify Dr. Daley's expectation that the census taken in June will swell the populations of holiday resorts like Blackpool at the expense of industrial towns like Blackburn. The staple industry of Blackburn is cotton spinning and weaving, and a noteworthy social feature is the extensive employment of female labour. At the census of 1911 there were 18,372 female weavers, 9118 of whom were married. There are a very large number of bottle-fed babies, and a high infant mortality rate—viz., 110 in 1920, as compared with 85 in the 96 great towns. Dr. Daley draws attention to the high neo-natal mortality. Thus of 311 infant deaths, 104 took place under one week, and 155 under one month. The maternal mortality from childbirth is also, Dr. Daley tells us, far too high, having been 5·9 and 5·6 per 1000 births for 1919 and 1920 respectively, as compared with 4·12 per 1000 births for England and Wales in 1919. There is a low birth-rate, which rose from 14·0 in 1919 to 20·1 in 1920. Dr. Daley has a good deal to say about the smoke nuisance, and instances Pittsburg, U.S.A., as an example of what can be done. He adds that there are 190 factory chimneys on the register; 92 are provided with smoke-consuming appliances, including five installed in 1920. Smoke observations, each of an hour's duration, were taken on 155 occasions. Twenty-eight chimneys emitted black smoke in excessive quantities. This means that many factories in Blackburn are continually breaking the law as regards the black smoke nuisance. There is no mention of any legal proceedings. We hope Dr. Daley will be successful in inducing his authority to start a really vigorous campaign on this question.

WIGAN.

Dr. Fred E. Wynne states in a farewell report as M.O.H. for Wigan that the estimated population for 1920 was 90,806; the birth-rate 30·61; the corrected death-rate, 15·92; the infant mortality rate, 124; the death-rate from pulmonary tuberculosis, 0·83, and from other tuberculous diseases, 0·19. Dr. Wynne points out that the reduction in the general death-rate still leaves it considerably in excess of that of the 96 great towns, and that the infant mortality rate is "still far from satisfactory." He is glad to report the resumption of the privy-conversion work. There are still over 1500 to be dealt with. There are two infant clinics; and Dr. Wynne points out that a large number of cases are referred to private practitioners, and is convinced that "the clinics, so far from competing with private practitioners, must considerably increase their clients." Dr. Wynne combats the idea that milk has been given away indiscriminately, and points out that in every application for free milk the applicant has to bring a wages statement signed by the employer. An interesting diagram showing the relation between the incidence of tuberculosis and the percentage of insanitary houses in each ward of the borough is given. Dr. Wynne notes that the results will be disconcerting to those who believe that in re-housing alone will be found the solution of the tuberculosis problem. Lindsay ward, with the highest general death-rate and the highest percentage of insanitary houses, has the lowest incidence of tuberculosis, while St. Patrick's ward, with the lowest percentage of insanitary houses, has the highest incidence of tuberculosis. Dr. Wynne explains this anomaly by the large proportion of Irish people resident in St. Patrick's ward, and expresses his belief that the Irish are susceptible to tuberculosis, and that the Western Celts and their descendants born in England do not as a rule adapt themselves readily to urban and industrial conditions. For the rest, the incidence of tuberculosis is highest in the centre of the town, and the moral is to get the people away from this centre. Dr. Wynne approves Miss Octavia Hill's system, and calls also for help in putting a stop to the pollution of the atmosphere by smoke, both domestic and industrial, and a more rigorous isolation of advanced and highly infectious cases of the disease.

As school medical officer, Dr. Wynne records the most important event of the year—the beginning of dental inspection and treatment, and includes in his report an appeal addressed by the school dentist, Mr. Townend, to parents on the importance of the care of their children's teeth. With regard to verminous conditions, Dr. Wynne makes the suggestion that the course of "nature study" given in the schools should include demonstration on the life-history of the louse. No progress has been made with the provision of the new school clinic, for which plans have been completed and which is urgently needed.

SCHOOL MEDICAL SERVICE.

BRISTOL.

THIS university city has an average school attendance of 50,000, half of whom pass annually through the doctor's hands. Of 18,003 who underwent routine examination, 576 were found to be suffering from anæmia, 397 from organic heart disease, 475 from malnutrition, and 4417 from defective vision. There were 59 cases of definite and 151 of suspected pulmonary tuberculosis. Nose and throat defects accounted for 2916, ear disease for 254, and defective hearing for 398. The great majority of these ailing children were treated at the school clinics. An increase of 59 per cent. is reported in the clinic cases which, the report states, would be untreated were it not for the authority's scheme of treatment. These cases consist for the most part of chronic ailments. Only five out of 1452 children failed to get the spectacles prescribed for them. One special school has a clinic on the premises, an especially helpful arrangement in the case of physically defective children who travel with difficulty. The staff of the school medical department has been strengthened by the appointment of specialist officers and work in the secondary school has begun. There are, so far, no nursery schools, but classes for children with defective sight and defective hearing are at work. Yet the stable-door is still unlocked, for the authority has not yet seen its way to arrange for treatment for children below school age, and as Dr. R. A. Askins states in his report, the majority of crippling defects start before this age. Scabies is rapidly on the decline, but impetigo remains high. It would be of interest to correlate this latter disease with nutrition. Infectious diseases ran rathe high, but Bristol is quite up to date in its method o dealing with these; one school only was closed. The statement made in this report that head measurements and mental capacity are not related cannot be definitely determined from the figures set forth here; these might have been influenced by age distribution, and they are, moreover, at variance with the extensive recent investigations of Berry and Porteus.

KENT.

Dr. Alfred Greenwood's report on the school medical work in Kent shows steady effort with corresponding progress. The closest coöperation exists between the public health and the school medical services, the infant welfare centres being under the school medical

Child-Study Society.—A lecture entitled "The Supernormal Child" will be given in the botanical theatre of University College, London, on Wednesday, Jan. 4th, 1922, by Robert Rusk, M.A., Ph.D. Dr. C. W. Kimmins will be in the chair.

Harveian Society.—The annual general meeting of this Society will be held at the Medical Society's Rooms, 11, Chandos-street, London, W., on Thursday, Jan. 12th, 1922, at 8.15 p.m., when the election of officers for 1922 will take place, and Dr. G. de Bec Turtle will deliver the presidential address on "Some Points on Spasm in the Alimentary Tract." A short musical programme has been arranged.

Medical Reciprocity with Belgium.—The Belgian Academy of Medicine, which has been requested by the Minister of the Interior to give its opinion on a proposal by the British Government for an Anglo-Belgian agreement providing for the reciprocal exercise of medical practice, has appointed a special commission to report on the matter. *The Academy itself is stated to be in favour of the scheme.*

Third International Congress of the History of Medicine.—At a general meeting held at the Royal Society of Medicine on Dec. 21st the following were elected officers of the Congress:—President of Honour: Sir Norman Moore. President: Dr. Charles Singer. Treasurer: Mr. W. G. Spencer. General Secretary: Dr. J. D. Rolleston. Vice-Presidents: Sir D'Arcy Power, Dr. Tricot-Reyer, Dr. E. Jeanselme, Dr. E. Ménétrier.

Mr. Frederick Walter Way, M.R.C.S., L.S.A., who died at Portsmouth on Dec. 21st at the age of 87, had retired from practice for many years. He entered St. Thomas's Hospital in 1852, qualified in 1856, and held house appointments at the Northampton General Asylum and at the Stourbridge Dispensary, afterwards becoming surgeon to the Royal Portsmouth Hospital. He married a daughter of the Rev. J. W. Banks, and their son who, like his father, was a student at St. Thomas's Hospital, is in practice at Southsea.

National Association for the Prevention of Infant Mortality.—A course of advanced lectures on infant care, for infant welfare workers, teachers, and mothers, will be held at the Lecture Hall, Carnegie House, 117, Piccadilly, London, on Mondays, at 6 p.m. from Jan. 23rd to April 10th, 1922. The syllabus includes the following lectures: The Normal Development of the Fœtus, by Dr. T. W. Eden; Venereal Disease in relation to Motherhood and Infancy, by Mrs. Scharlieb; Physiology of Pregnancy and Labour, by Lady Barrett; The Scientific Principles underlying Artificial Feeding, by Dr. Eric Pritchard; The Nervous Child, by Dr. David Forsyth; Skin Diseases in Young Children, by Dr. Henry MacCormac; Tuberculosis in Infancy and Childhood; by Dr. T. N. Kelynack; The Prevention of Ear and Throat Troubles, by Mr. Philip Franklin; An Infant Welfare Programme, by Dr. Harold Scurfield; How to Conduct an Infant Consultation, by Dr. Harold Waller; Mental Deficiency in Children under School Age, by Dr. A. F. Tredgold; The Psychology of Early Childhood, by Dr. H. Crichton Miller. Tickets (for the whole course of 12 lectures, 8*s.* 6*d.*, for any one lecture, 1*s.* 3*d.*) may be obtained from Miss Halford, Hon. Secretary, National Association for the Prevention of Infant Mortality, 117, Piccadilly, London, W.1.

Fellowship of Medicine and Post-Graduate Medical Association.—A special post-graduate course in general medicine will be held from Jan. 9th to Feb. 18th, 1922, at the following hospitals: Bethlem Royal Hospital, Cancer Hospital, Chelsea Hospital for Women, Hospital for Consumption and Diseases of the Chest, Hospital for Epilepsy and Paralysis, Middlesex Hospital, National Hospital for Diseases of the Heart, Paddington Green Children's Hospital, W., Royal Westminster Ophthalmic Hospital, St. George's Hospital, St. Mark's Hospital for Diseases of the Rectum, St. Marylebone General Dispensary, St. Peter's Hospital, and Western Hospital. The syllabus for the first week includes five lectures and demonstrations at the Brompton Hospital; a post-mortem demonstration by Dr. R. Donaldson at St. George's Hospital; operations at the Chelsea Hospital by Mr. Victor Bonney, who will also give a demonstration on the Treatment of Prolapse, and by Mr. F. L. Provis, who will also lecture on X Ray Therapy in Gynæcology, and demonstrations at the same hospital by Mr. Aubrey Goodwin and Mr. L. C. Rivett; a lecture by Mr. J. Swift Joly at St. Peter's Hospital on Calculous Disease of the Urinary Organs, and a demonstration of infectious cases under treatment at the Western Hospital by Dr. R. M. Bruce. Further particulars will be found in our Medical Diary. The fee for the course is 15 guineas, and the names of those wishing to attend should be sent as soon as possible to the Secretary at the Fellowship of Medicine, 1, Wimpole-street, London, W. 1, to whom all inquiries should be addressed.

Memorial to a Medical Man.—On Dec. 18th, in Bath Abbey, a tablet was unveiled and dedicated to the memory of Dr. George Hely-Hutchinson Almond, Temporary Captain, R.A.M.C., who was killed in action at Caix, France, on August 9th, 1918. The tablet was erected by members of the medical profession in the city of Bath and the surrounding district; Dr. A. E. Norburn performed the unveiling ceremony in the presence of many of the late Dr. Almond's former colleagues.

General Hospital, Birmingham.—At a meeting of the governors, held on Dec. 23rd, it was decided that from Jan. 1st, 1922, all patients with three exceptions should be required to pay a maintenance charge at a rate not exceeding £2 2*s.* a week, according to their means. The exceptions are: (*a*) Such accident or urgent cases as are unable to pay; (*b*) other patients who provide an in-patient ticket and are unable to pay; and (*c*) employees and their dependents who provide a ticket through their employer or through a Works or Office Benevolent Fund subscribing directly to the hospital. It was further resolved that 1 per cent. of the amount received by the hospital owing to the adoption of the maintenance charge should be set aside to form a "Medical Staff's Equipment Fund," which should be placed at the disposal of the medical staff either for the purchase of special equipment or apparatus, or in any other way which, in the opinion of the staff, would be of benefit to the hospital. A year ago the board of management recommended a similar scheme to the governors which aroused considerable opposition on the part of working-class supporters, who offered, if the maintenance charge was dropped, to make good the sum required through a Hospital League which should collect money from the factories. The Hospital Saturday Fund felt that the League was trespassing on its ground and the other hospitals also opposed it. The League has now abandoned its collections in factories, but branches have been formed in various districts to make house-to-house collections. Already by the exertions of the Handsworth branch enough money has been collected to reopen 12 of the closed beds.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

Wednesday, Jan. 4th.

SURGERY: at 5.30 p.m.

Discussion: On "Post-operative Embolism and Infarction," to be opened by Mr. J. P. Lockhart-Mummery.

The following will contribute to the discussion:—Mr. Victor Bonney, Prof. Collingwood, Sir Charles Gordon-Watson, and Dr. Arthur Latham.

Members of other Sections are cordially invited to attend the above meeting.

Thursday, Jan. 5th.

OBSTETRICS AND GYNÆCOLOGY: at 8 p.m.

Specimen:

Mr. Beckwith Whitehouse: Tubal Lithopædion.

Short Communications:

Mr. Beckwith Whitehouse: Salpingotomy versus Salpingectomy in the Treatment of Tubal Gestation.

Mr. John B. Hunter (introduced by Dr. Blacker): Short History and Post-mortem Notes of an Interesting Case of Diffuse Carcinoma following Cancer of Cervix (illustrated).

Paper:

Mr. Aleck W. Bourne: Hyperthyroidism in Functional Menorrhagia.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.

Monday, Jan. 2nd.—2 p.m., Dr. Simson: Diseases of Women.

Tuesday.—2 p.m., Mr. Banks Davis: Diseases of the Throat, Nose, and Ear.

Wednesday.—2 p.m., Mr. Tyrrell Gray: Operations.

Thursday.—2 p.m., Mr. Bishop Harman: Eye Department.

Friday.—2.30 p.m., Dr. Pritchard: Visit to Medical Wards.

Saturday.—2 p.m., Dr. Owen: Medical Out-patients.

Daily:—10 a.m., Visit of Post-graduates to Wards. 2 p.m., In-patient, Out-patient Clinics and Operations.

IMPERIAL COLLEGE OF SCIENCE, South Kensington.

Wednesday and Thursday, Jan. 4th and 5th.—3 to 6 p.m. and 7 to 10 p.m., Physical Society and Optical Society's annual exhibition. Lectures illustrated by experiments will be given.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN, 49, Leicester Square, W.C.

Thursday, Jan. 5th.—6 p.m., Chesterfield Lecture. Dr. W. Griffith: Parasitic Diseases of the Skin.

regret having given currency in this country to what turns out to be an untrue statement published in the United States regarding the work of a charming and conscientious American colleague.

I am, Sir, yours faithfully,
W. BLAIR BELL.

Liverpool, Dec. 20th, 1921.

ENCLOSURE.

Copy of a letter from Dr. Dougal Bissell, 219, West 79th-street, New York, dated Dec. 1st, 1921.

MY DEAR DR. BELL,—I am sending you a letter received from Dr. Vineberg on the question of my "75 per cent. mortality" in the operation of interposition of the uterus for the cure of procidentia uteri, cystocele, &c. The letter speaks for itself, and I would be greatly obliged if you would have the error in your article, which, as you appreciate, places me in a most uncomfortable position, corrected in THE LANCET. A few words from you would be to a better purpose than any public statement I could make. The simple fact is that I have done comparatively few interposition operations, but I have never had a death, nor do I know of a death following this operation in the hands of any of my friends.

Cordially and sincerely yours,
(Signed) DOUGAL BISSELL.

Copy of a letter from Dr. Hiram N. Vineberg to Dr. Dougal Bissell, dated Nov. 23rd, 1921.

DEAR DR. BISSELL,—In your letter of the 11th instant you draw my attention to a quotation by Dr. Blair Bell, in a paper in THE LANCET from a statement I made, in a discussion of a paper by Dr. George Gray Ward, Junr., on the problem of cystocele in the *American Journal of Obstetrics and Gynecology*, 1919, lxxix., p. 677. I stated you had a mortality of something like 75 per cent. in following the method described by F. F. Simpson of reducing the size of the uterus when it was too large to be adaptable for interposition, and that you had abandoned the method as well as I had myself, on account of the dangerous suppuration that attended it.

I made the statement in good faith, having in mind the paper entitled A Subtotal Hysterectomy, &c., I heard you read at the meeting of the American Gynecology Society held at Pittsburgh, Pa., May 31st, June 1st and 2nd, 1917. My recollection of it was that in seven cases you had five deaths. This was firmly imbedded in my memory, as it was in that of another colleague who heard your paper and to whom I have spoken on the subject recently.

Since receiving your letter I have, for the first time, read your paper as published in the Transactions of the Society for the year 1917. I saw then how I must have gained the erroneous impression. In it you state than in seven cases the indications for the operation were fibroid of the uterus, procidentia, and cystocele. That evidently impressed me as the number of cases in which the uterus was enlarged, and its reduction in size indicated. Further, you state that serious infection occurred in five of the cases.

Through faulty hearing, enhanced by poor acoustics, which most of our meeting rooms have, I must have understood you to state that you had had five deaths in the series in which the uteri were enlarged by fibroid condition, and had to be reduced in size. Of this I am certain, I carried away with me the idea that out of seven cases you had had five deaths. Hence the statement of something like 75 per cent. mortality.

But on a careful reading of your paper I find that the operation had been performed upon 31 cases and that in the series there were five serious infections with only one death. The mortality rate, therefore, for the entire series was only 3 per cent. instead of the "something like 75 per cent."

I am greatly chagrined with myself for the egregious misconception I gained from listening to the reading of your paper. Please accept my most sincere apology for the error and for the injustice unwittingly done you. It shows very forcibly how unsafe it is to rely solely upon conceptions gained from hearing a paper read. As far as I know it is the first time my hearing has played me such an unfortunate trick.

I can only say the incident has taught me a very striking lesson, from which I hope to benefit in the future. I sincerely hope my confessed and deeply regretted error will receive as much publicity as the original statement.

Very sincerely yours,
(Signed) HIRAM N. VINEBERG.

INFECTIOUS DISEASE IN MAURITIUS.

To the Editor of THE LANCET.

SIR,—With reference to the notes on "Influenza in Mauritius" in THE LANCET of Oct. 1st, Mr. A. F. Fokeer is wrong in exonerating the Indians from a share in the insanitary condition of the island. The majority of the Indian population of Mauritius are coolies, with no idea of sanitation whatever. On the sugar estates they live in thatched huts built in crowded "camps." There is no drainage; the water-supply is taken from the nearest polluted stream and conveyed to the estate in open canals, in which soiled linen is washed and in which every one bathes as he pleases. On the estate the water is distributed by means of smaller open canals, which also serve the purpose of open sewers.

This was the state of affairs on sugar estates when I lived in the island many years ago, and I am told that things are still in the same condition. In the smaller towns and villages the same conditions obtain, and even Port Louis, the capital, is notorious for its evil smell, especially in the slums, though of late some efforts have been attempted to improve matters. Port Louis and Curepipe, however, have a good water-supply.

The Board of Health of the island imposes stringent regulations regarding the vessels that visit the island from foreign countries, especially India, but the antiquated measures adopted to deal with infected ships are the talk of the shipping world. Epidemic disease in any port of the world seldom fails to visit the island in its worst form. At present, it appears, there is an epidemic of enteric fever.

I am, Sir, yours faithfully,
C. L. D'AVOINE, M.D. Brux.

Byculla, Bombay, Oct. 21st, 1921.

Obituary.

JOHN ELLIOTT, M.D., B.S., F.R.C.P. LOND., F.R.C.S. ENG., B.SC.,

CONSULTING PHYSICIAN TO THE CHESTER ROYAL INFIRMARY.

LAST week we recorded the untimely death of Dr. John Elliott, who occupied a distinguished position as physician-consultant in Chester and North Wales. Born in 1861, Dr. Elliott was educated at Owens College, Manchester, and St. Bartholomew's Hospital, and graduated in two faculties of the University of London, becoming B.Sc. with honours in 1880 and M.B., also with high honours and a gold medal, in 1885; he also obtained the gold medal in the examination for the B.S. in 1886. Dr. Elliott proceeded further to equip himself with the highest qualifications open to a member of the profession in both of its main branches, being elected to the Fellowship of the Royal College of Physicians of London (1886) and that of the Royal College of Surgeons of England (1908). He held the post of house surgeon at his teaching hospital, and then became resident surgical officer at the Birmingham General Hospital. He was later elected a physician on the staff of the Chester Royal Infirmary, and then settled permanently in consulting practice in Chester. His advice was eagerly sought throughout North Wales, and he was always a source of help to his junior colleagues at the Chester Royal Infirmary. Dr. Elliott's services to the community were not confined to his medical activities. He was a member of the Chester City Council from 1895 to 1898, and from 1913 he was a member of the Commission of the Peace for Chester, while he was an active member of the Chester Agricultural Society. During the war Dr. Elliott rendered valuable services, and for this work he received the O.B.E. His recent protest made in the High Court against the disclosure of confidential information in certain circumstances, as between patient and doctor, will be fresh in the memory of many of our readers. He took a keen interest in the applications of optics to colour photography, in the practice of which he was an adept artist. In him the medical profession has lost an accomplished and all-round exponent of our science and art.

Medical News.

UNIVERSITY OF CAMBRIDGE.—At the Third Examination for Medical and Surgical Degrees, held recently, the following candidates were successful:—

Part I., Surgery, Midwifery, and Gynæcology.—L. H. Bartram, W. T. Beswick, T. A. Butcher, S. P. Castell, R. S. Corbett, N. R. Cunningham, E. Donaldson, J. G. Drew, W. F. Eberlie, H. V. Edwards, A. A. Gemmell, L. B. Hartley, C. B. Hawthorne, J. B. Leather, W. B. A. Lewis, A. G. F. McArthur, C. F. McLean, B. Mountain, R. W. Nichol, R. R. Powell, A. A. Prichard, A. E. Roche, J. C. Russell, H. Spibey, and R. R. Traill.

EXAMINATION FOR THE DEGREE OF M.CH.

R. St. L. Brockman.

UNIVERSITY OF LONDON.—At examinations held recently the following candidates were successful:—

M.D. EXAMINATION.

Branch I., Medicine.—Laurence Ball (University medal), Birmingham University; Loswel I. Braun, St. Bart.'s Hosp.; Nora A. Crow, London Sch. of Med. for Women; Edward E. Lightwood and Frank Portas, Westminster Hosp.; Walter M. A. Rahman, Univ. Coll. Hosp.; Noel O. Richards, London Hosp.; Ernest W. Wade, Univ. Coll., Bristol; and Charles H. Warner, Middlesex Hosp.

Branch IV., Midwifery and Diseases of Women.—Margaret M. Basden, London Hosp.; Simeon M. Cohen, Univ. Coll., Cardiff, and St. Bart.'s Hosp.; Janet McAllister McGill (University medal), London Sch. of Med. for Women and St. Mary's Hosp.; Percival G. Quinton, Univ. Coll. Hosp.; Elisabeth H. Schwab, London Sch. of Med. for Women; and Raymond Theron, London Hosp.

Branch V., State Medicine.—George W. Shore, King's Coll. Hosp.

Branch VI., Tropical Medicine.—Charles T. Maitland (University medal), St. Bart.'s Hosp. and London Sch. of Trop. Med.

M.S. EXAMINATION.

Branch I., Surgery.—Ranald M. Handfield-Jones, St. Mary's Hosp.; and Walter Salisbury, Bristol University and London Hosp.

A course of six public lectures on the Current Work of the Biometric and Eugenics Laboratories will be held at the University of London on Wednesdays in February and March, 1922, at 8 P.M. On Feb. 15th Prof. Karl Pearson, F.R.S., will lecture on Side-lights on the Evolution of Man: from the Knee-joint; on the 22nd Miss Ethel M. Elderton, Galton Research Fellow, will lecture on the Inheritance of Intelligence; and on March 1st Dr. Percy Stocks will discuss a Scheme of Anthropometric Measurements in the Biometric Laboratory. The Relation of Caries in the Teeth of School Children to Health and Home Conditions will be dealt with by Miss E. C. Rhodes on March 8th; Dr. Julia Bell will speak on the Inheritance of Certain Types of Blindness; and the closing lecture of the series will be delivered on March 22nd by Dr. M. Greenwood on Occupational Mortality. The lectures are open to the public without fee, but as only a limited number of seats are available, admission will be by numbered ticket for each lecture, for which application should be made to the Secretary, Galton Laboratory, University College, London, W.C. 1.

UNIVERSITY OF ABERDEEN.—The following have graduated in medicine as the result of the special examination for ex-Service students:—

C. A. Aymer, Isobel M. G. Bisset, William S. Cochar, Henry B. Cook, Alex J. Curr, Nellie S. Diack, Isabella R. Gordon, J. Grant, W. P. Jordaan, D. F. McGregor, N. M. Maclennan, R. Macleod, J. W. Macrae, D. Meldrum, W. J. Meldrum, J. I. Milne, Victor E. Milne, William G. Murray, J. D. Pole, J. Rannie, C. Reid, H. Ritchie, Charles Shapiro, J. C. Souter, Harriet J. S. Taylor, M. Taylor, V. M. M. Watson, Annie T. West. J. C. Souter graduated with second-class honours, while N. M. Maclennan, W. J. Meldrum, Victor E. Milne, and J. C. Souter passed their final professional with distinction.

UNIVERSITY OF MANCHESTER.—At examinations held recently the following candidates were successful in the subjects indicated:—

FINAL M.B. AND CH.B. EXAMINATION.

R. S. van Aalten, G. H. Buckley, Vincent Chadwick (second-class honours), N. S. Craig, O. M. Duthie, H. E. Emmett, Caroline M. Edwardes-Evans, William Geraghty, Marguerite F. Johnstone, Jessie Kilrow, W. L. Martland, Margaret Pownall, Harry Rosenthal, J. W. Smith, S. N. Taylor, Nora N. Walker, and James Worthington.

Forensic Medicine.—Reginald Anderton, H. P. Fay, F. W. W. Fox, C. B. Kirkbride, and A. A. Pomfret.

Medicine.—Samuel Adler and Dorothy M. L. Dyson.

Obstetrics.—R. J. Allison and Dorothy M. L. Dyson.

Surgery.—R. J. Allison.

THIRD M.B. AND CH.B. EXAMINATION.

Pathology.—K. V. Bailey, Gwendoline A. G. Edwardes-Evans, and G. B. Lord.

Pharmacology.—Hanna Aziz, Soloman Bernstein, Arnold Brown, Mary S. Davies, Charles Eccleston, Madge E. Edwards, R. A. Ferguson, R. W. Fairbrother, E. St.G. Gilmore, Anne H. Glancy, W. G. Howson, Alun M. Jones, A. C. Kelly, V. F. Lambert, G. F. S. Parker, Miles Parkes, Kate B. Scott, Dorothy Simmons, Marjorie Thompson, and E. J. Warburton.

DIPLOMA IN DENTISTRY.

Final Examination.—M. H. Duxbury, J. L. Halliwell, A. V. Littlewood, H. V. Longson, and G. H. Wood.

Systematic Surgery.—S. J. Gray.

Dental Surgery.—A. N. Place.

Dental Prosthetics.—S. J. Gray and A. N. Place.

UNIVERSITY OF LEEDS.—A congregation of the University was held at the Medical School on Dec. 22nd, presided over by Sir Michael Sadler, the Vice-Chancellor, when the following degrees were conferred:—

DOCTOR OF MEDICINE.

Louis Gordon.

BACHELOR OF MEDICINE AND BACHELOR OF SURGERY WITH HONOURS.

First Class: John T. Blackburn and Digby Chamberlain.

Second Class: Donald I. Currie, Henry Duck, William H. Leake, Hilda Thistlethwaite, John L. Wesley-Smith, and Charles H. Wilson.

BACHELOR OF MEDICINE AND BACHELOR OF SURGERY.

Alfred L. C. Harron, Ralph Hodgson, Eric E. Holdsworth, Marion Knowles, William A. D. Lawson, Elsie E. McNeice, Horace C. Petch, Osra Muriel Phillips, Phyllis M. Platt, Douglas Robertson, and Harriette A. Wilson.

In examinations held recently the following candidates have been successful:—

FINAL M.B., CH.B. EXAMINATION.

Part I.—J. Atkinson, Marjorie Baxter, W. H. Bean, Aileen M. Claye, F. Clegg, I. H. Cohen, L. Cohen, M. Cohen, R. Crockatt, Dorothy M. Edgcombe, H. Fallows, J. Freeman, H. A. Hellewell, S. Hyman, Marjorie M. Jackson, R. H. Lodge, A. A. Masser, P. Oberman, J. R. Oddie, J. E. Outhwaite, Gwendoline F. Prince, P. Rosenbloom, G. H. Sellers, H. Sheard, D. M. Sutherland, A. L. Taylor, G. M. Wadsworth, A. Walbank, G. F. Walker, J. S. Walker, Gretta M. Wardle, and R. Wood.

Part II.—Edith Ghosh, S. Levy, and Jessie Sheard.

FINAL L.D.S. EXAMINATION.

Part I.—G. C. Channon, A. D. Clubb, J. C. Crossley, A. D. Page, and G. B. Reid.

Part II.—N. L. King, L. Temple, and F. L. Tomlinson.

DIPLOMA IN PUBLIC HEALTH.

H. J. G. Wells.

This year the University has instituted a Diploma in Nursing, the first of its kind in the Empire. The regulations of the diploma have been founded on the curriculum of training in the Leeds General Infirmary. The promoters of this training school for nurses have been fortunate in the coöperation of the matron of the infirmary, Miss E. S. Innes, and have selected her as recipient of the first diploma conferred. Five other nursing diplomas were awarded.

ROYAL COLLEGE OF PHYSICIANS AND ROYAL COLLEGE OF SURGEONS IN IRELAND CONJOINT EXAMINATIONS.—At examinations held recently the following candidates were successful:—

FINAL PROFESSIONAL EXAMINATION.

Edward S. Becker, Eric J. Benson, William H. Browne, John F. J. Cleary, John J. Clune, Ambrose Doran, William C. Dwyer, Jeremiah F. Enright, Mea Williams Frazer, John J. Fitzsimons, John MacFarlane Gray, Michael P. P. Higgins, Charles S. Hills, James H. Lawlor, Matilda G. Neill, Richard H. Nightingale, John O'Leary, Gordon S. Rutherford, and Thomas G. Whitcroft.

DIPLOMA IN PUBLIC HEALTH.

Vincent J. Glover, Harold L. Mooney, and John A. Musgrave.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—At recent examinations the following candidates were successful:—

FINAL FELLOWSHIP EXAMINATION.

William J. Dunlop, Frederick Gill, Sylvester J. Healy, and William Napier.

ROYAL SANITARY INSTITUTE.—Maj.-Gen. J. E. B. Seely has consented to preside at the thirty-third congress of this Institute, to be held at Bournemouth from July 24th to 29th, 1922.

POST-GRADUATE COURSE ON ORTHOPÆDICS.—A course on Orthopædics will be held by Dr. F. Calot, chief surgeon to the Hôpital Rothschild, of the Institut Orthopédique de Berck, at his Paris clinic from Jan. 23rd to 29th, 1922, from 2 P.M. to 7 P.M. daily. The course is designed for medical men and students, native and foreign, and demonstrations in English and Spanish will be given. The fee is Fr.150. A detailed programme and any other information required can be obtained from Dr. Fouchet, Institut-Calot à Berck-Plage, or from Dr. Collew, Clinique-Calot, 69, Quai d'Orsay, Paris.
